Welch, J. B., M.B., M.R.C.S.E., has been appointed an Acting Physician to the Birmingham and Midland Free Hospital for Sick Children, vice Mackey, resigned.

Young, C., M.D., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Yarm District of the Stokesley Union, Yorkshire.

Births, Marriages, and Deaths.

BIRTHS.

BRODRIBB.—On the 5th inst., at Watford, the wife of Charles A. Brodribb, M.R.C.S.E., of a son.

DAVSON.—On the 1st inst., at Campden Villa, Maida-vale, the wife of S. H. Davson, M.D., of a son.

HATHERLY.—On the 2nd inst., at Wellington-street, Park-side, Nottingham, the wife of H. R. Hatherly, L.R.C.P.Ed., of a son.

KEITH.—On the 13th of Sept., at Nuwara Eliya, Ceylon, the wife of William Gregory Keith, M.B., C.M., L.R.C.P.Ed., L.R.C.S.Ed., Assistant Colonial Surgeon, of a daughter.

MACKINNON.—On the 1st inst., at Aldershot, the wife of Surgeon-Major C. Mackinnon, Army Medical Department, of a son.

MIDDLETON.—On the 7th inst., at Manorhead, Stow, N.B., the wife of Dr. James Middleton, of a daughter.

NEWBERRY.—On the 8th inst., at Burgess Hall, Leeds, Kent, the wife of W. J. Newberry, M R.C.S.E., L.S.A.L., of a daughter.

SAUNDERS.—On the 6th inst., at Lower Seymour-street, Portman-square, the wife of C. E. Saunders, M.D., of a son.

STILWELL.—On the 4th inst., at Beckenham, the wife of R. R. Stilwell, M.D., of a son.

MARRIAGES.

JAMISON—GREEN.—On the 4th inst., at the Parish Church, Weybridge, Arthur J. Jamison, M.D., to Isabella, daughter of the late Rev. H. Green.

LUCE—RYAN.—On the 4th inst., at Winchester Cathedral, James Johnstone Luce, M.D., of Stratford-on-Avon, to Mary, widow of the Rev. John Ryan, Curate of Holy Trinity Church, Southampton, eldest daughter of the late Wm. Barry, Esq., of Kilbarry, Co. Cork, and grandniece of the late Matthew De Rinzy, Esq., D.L., of Clobemon Hall, Co. Wexford, Ireland.

SHORTT—ROGERS.—On the 9th of Sept. (by special licence), at St. John's Church, Bangalore, John Shortt, M.D., M.R.C.P.L., F.L.S., &c., Surgeon-Major and Inspector of Vaccination, Madras Presidency, to Annie Julia Henrietta, eldest daughter of Surgeon-Major C. J. Rogers, Zillah Surgeon, of Coimbatore.

DEATHS.

ANDERSON.—On the 31st ult., at Ajaccio, Corsica, James R. Anderson, L.R.C.S.Ed., retired Staff-Surgeon R.N., aged 40.

BEADLES.—On the 4th inst., at Park House, Forest-hill, John N. Beadles, M.R.C.S.E., late of Broadway, Worcestershire, aged 73.

CHARTRES.—On the 31st ult., at Clifton House, Hampstead, J. S. Chartres, M.D., Surgeon-Major Army, aged 47.

DAVIS.—On the 2nd inst., at Linden House, Winkleigh, Devon, Wm. H. Davis, M.R.C.S.E., aged 44.

HAMMOND.—On the 3rd inst., at Market-street, Cambridge, J. Hammond, F.R.C.S.E., aged 72.

LLOYD.—On the 2nd inst., David Lloyd, M.R.C.S.E., of Carmarthen.

M'GILLIVRAY.—On the 25th ult., at Kilmore, Co. Argyll, Geo. M'Gillivray, M.D., aged 49.

PASSMORE.—On the 4th inst., at Brighton, John Geo. Passmore, M.R.C.S.E., aged 59.

PULLAN.—On the 2nd inst., at Epworth, Lincolnshire, Richard Pullan, M.R.C.S.E., formerly Assistant-Surgeon R.N., aged 82.

SARVIS.—On the 4th inst., Thomas Sarvis, M.D., of Bethnal-green-road, Medical Officer of Health for Bethnal-green, aged 54.

SIMPSON.—On the 3rd inst., at Priestley-road, Warwick, John H. Simpson, Surgeon, aged 68.

SPENCER.—On the 1st inst., at Stoke Newington, John Spencer, M.R.C.S.E., aged 61.

STRADLING.—On the 5th ult., at Glastonbury, F. R. Stradling, Surgeon, aged 56.

TAIT.—On the 22nd ult., at Dunse, John Tait, L.R.C.S.Ed., aged 56.

[N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*]

Notes, Short Comments, and Answers to Correspondents.

THE SKIPTON GUARDIANS.

THE proverbial and often false economy of so-called guardians of the poor is exemplified in the recent action of the Skipton Board towards their medical officer, who, after holding his appointment for a year, has applied for an advance of salary, basing his claims thus—1st, the salary has been the same for the past twenty-five or thirty years; 2nd, an Infirmary for Contagious and Infectious Diseases for the whole union has been added to the workhouse without any additional salary; and 3rd, the number of inmates in the workhouse has been nearly trebled. To the intelligent minority of the guardians their medical officer's claim seemed most reasonable; but on a vote it was decided to give no advance. The workhouse doctor consequently resigned, and as his professional brethren in the town are sensible of the justice of his claim, they all refuse to apply for the post. In this dilemma the guardians are advertising the appointment, and it now remains to be seen whether anyone, or who, will assist the guardians in frustrating the apparently just claims of their medical officer. Considering that there is not a breath of complaint against his professional skill or attention to the sick poor, we hardly think any medical man would be justified in offering himself to fill the vacancy.

Mr. G. D. O. Thomas.—Declined with thanks.

MEDICAL OFFICERS OF HEALTH: THEIR DUTIES AND THEIR RELATIONS TO PRIVATE PRACTITIONERS.

B. U. R. asks a series of questions, which we proceed to answer *seriatim*:—1. "Is it the duty of a medical officer of health to see those who are sick?" By the regulations of the Local Government Board, a medical officer of health is required to "inquire into and ascertain by such means as are at his disposal the causes, origin, and distribution of diseases within his district"; also, on receiving information of the outbreak of any contagious, infectious, or epidemic disease of a dangerous character within his district, "to visit the spot without delay, and inquire into the causes and circumstances of such outbreak, and advise the persons competent to act as to the measures which may appear to him to be required to prevent the extension of the disease, and, so far as he may be carefully authorised, assist in the execution of the same." These duties can only be carried out with a definite knowledge of the nature of the disease, and it is left to the judgment of the medical officer how to obtain this. He has no right of entry to the sick without the consent of the sick persons themselves or those in charge, and he is not exempted by the above requirements from the customary professional courtesies, unless, indeed, the medical attendant should refuse to aid or co-operate with him.—2. "Is it his duty to see them two or more times?" Such a duty might arise under certain difficulties of diagnosis, or of applying necessary means of preventing the spread of the disease; but clearly it is one that, where there is an ordinary medical attendant, must be strictly carried out in co-operation with him, unless, indeed, the latter refuse to co-operate.—3. "Is it his duty to make suggestions as to treatment in the medical attendant's absence, and without his consent?" Unquestionably not. This would be equally a breach of professional etiquette and of his proper duties. These are limited to measures of prevention, and here circumstances may arise in which it may be his duty to make suggestions; but always subject to the consideration that he has no right of interference with the medical attendant in charge, unless with the assent of the latter, or that he is satisfied that measures necessary for the safety of the community are being neglected.—4. "Is it his duty to enter and examine a house in which there is no illness, and that is not suspected of being in an insanitary condition?" It may be a duty for him to satisfy himself that a house is free from sickness or insanitary states during inquiries into the distribution, causes, or prevalence of disease.—5. "Supposing him to condemn some cesspool or drainage arrangement, is it his duty to say what must be done, or leave it to be done by the occupier, on the chance of his approving or not, as the case may be, when it is finished?" It is no part of his duty to say what *must* be done, unless some bye-law of his authority exist touching the matter which empowers him to be imperative; but he has a duty of seeking by reasonable advice and suggestion to prevent what is to be done being wrongly executed.

"NOBLESSE OBLIGE."

To the Editor of THE LANCET.

SIR,—The attention of the Committee of this hospital has been called to a letter in last Saturday's LANCET, written by Mr. R. J. Metcalfe, of Beccles. I am requested by them, as their honorary secretary, to write to you on the subject of that letter. These are two, and they should be kept distinct from each other.

1. Mr. M.'s own treatment by "the authorities of the North Cambs Hospital"; and
2. The propriety of a certain regulation in this hospital.

1. On the first subject Mr. M. complains of discourtesy on the part of our chairman and our resident surgeon. The former, the Rev. Canon Scott, Vicar of Wisbeach, is as far removed from discourtesy or any sort of unkindness as black is from white. The latter gentleman is also utterly incapable of any such conduct as is imputed to him. We ourselves, as a Committee, and all others who have personal knowledge of these two gentlemen, are quite convinced of the impropriety of any such charge of discourtesy. Your correspondent's feelings seem to have been overwrought by the painful circumstances in which he was placed in consequence of his father's sad illness. We have been told that to have extemporised a millboard splint would have taken him but a short time, far less than the hours occupied in journeying to and from Wisbeach on the occasion.

2. As to the rule itself, it has been made the subject of long and anxious consideration and discussion. Under the peculiar circumstances of this hospital, the Committee—who have met this day, thirteen in number—have again, after reading your correspondent's letter, decided to let the rule remain as it is. It is quite inaccurate, however, to describe as the effect of the rule "that no instrument or appliance was allowed to be taken out of the hospital." The rule or minute is as follows. It was passed in this form on January 27th, 1874:—"That no furniture, surgical instruments and appliances, or property of any description belonging to the hospital, be removed from the premises for any purpose whatever without the special permission of the Committee, or, in case of emergency, of one of the trustees, and with the concurrence of the house-surgeon and one of the other medical officers."

Expressing our regret that Mr. Metcalfe should have mixed up mere personalities and imaginary grievances with the subject for public consideration, and that THE LANCET should have been made the vehicle of such irrelevant matter, I am, Sir, on behalf of the N.C.C.H. Committee,

Your obedient servant,
ALFRED J. PERRY, Hon. Sec.,
Vicar of St. Augustine's, Wisbeach.

North Cambs Cottage Hospital, Wisbeach, Nov. 2nd, 1875.

⁂ We regret that the Committee should have confirmed a rule which has operated so harshly. We are sure that the subscribers of a hospital would regret that a splint had been refused to a surgeon with a broken arm under the circumstances of this case. It would be quite enough, to protect the surgical apparatus of a hospital, to require the house-surgeon to be responsible, and to enter any loan of it in a special book.—ED. L.

CONSTANT WATER-SUPPLY.

IT is gratifying to perceive even faint indications of the eventual satisfaction in London of what we have repeatedly urged as one of the prime necessities of urban populations—a constant water-supply. The East London Waterworks Company have given notice of their intention to apply the constant service, from the 1st of March to 1st of April, 1876, to certain areas in the parishes of St. John (Hackney), St. Matthew (Bethnal-green), and St. Leonard (Shoreditch). The Kent Waterworks Company have also signified their intention to give a constant supply of water to certain portions of the parish of Woolwich. We have advocated the constant service system solely in the health interests of the community; but there appear to be some people so sanguine in respect of its potent results as to predict that its adoption would have the effect of closing half the Fire Insurance Offices, and of reducing the Fire Brigade establishment to one-half its present proportions.

L.R.C.P. Lond.—Every information respecting it may be obtained by making application to Dr. Paget, Cambridge University.

THE FLEXIBLE STETHOSCOPE.

To the Editor of THE LANCET.

SIR,—In reference to the flexible stethoscope recently introduced by Drs. Reid and Morison, I may state that I have been in the habit of occasionally using one identical in principle for three or four years. The idea was "suggested" to me by observing a broken stethoscope on the mantelpiece. I cut off the chest-piece with about two inches of the stem, and then cut away the ear-piece until, by cutting and sand-papering the remainder, it exactly fitted my meatus, leaving also about two inches of the shaft attached. Upon uniting the chest- and ear-pieces with about two feet of common elastic tubing, I obtained a flexible stethoscope which exactly fitted my meatus, and which was quite equal in acoustic properties to any other that I ever saw. Subsequently, being annoyed a little by the concussion caused by the application of the chest-piece, and also to lessen the roaring, I bored a small oblique hole in the ear-piece.

If any medical man likes to follow out these directions, I guarantee him a flexible stethoscope in every respect (except in appearance) equal to any that he can buy, and which will have the great advantage of exactly fitting his ear.

Another recommendation of this stethoscope is that the wood is warmer to the ear, and not so apt to set up irritation or give cold. I have found it of some use in auscultating babies, the backs of fever patients, hysterical females who cannot bear the pressure of the ordinary stethoscope, and the uterus per vaginam, to ascertain the seat of the placental attachment. For this last purpose it is very well adapted; but it is better, for obvious reasons, to tie tightly a piece of gutta-percha tissue over the chest-piece before using it.

And now I have said all I can in its favour. It has all the usual faults which I have before found in flexible, air-conducting stethoscopes—viz., confusion of sounds from too great reverberation, and adventitious sounds arising from the friction of the hand holding the chest-piece with it. The latter can, with practice, be instantly distinguished from chest-sounds; but the first leads to that greatest of all faults of a stethoscope, indistinctness of definition, and, being obviated by nothing that I know of, is so great an objection as to be fatal to the use of the flexible stethoscope under any circumstance in which the ordinary stethoscope can be used with any approach to comfort.

The flexible stethoscope conducts plenty of sound, in fact more than the ordinary stethoscope considerably; but it is the same with it as with the microscope, in which, as every practical worker knows, low power and good definition is greatly to be preferred to high power and bad.

Yours obediently,
Blackpool, Nov. 8th, 1875. WM. HARDMAN.

To the Editor of THE LANCET.

SIR,—In your last two impressions letters have appeared from Drs. Hutchinson and Balbirnie with reference to the flexible stethoscope. The former ascribes to Dr. Sibson, and the latter to Dr. Golding Bird, the use of such an instrument. The instruments known as having been used by these gentlemen in no way resemble that advertised by Messrs. Arnold and Sons, except in that they are flexible. Both *were* constructed much shorter, and both *had* flat ear-pieces. When Dr. Reid and I gave a plan of the instrument in question to the makers, these were the only flexible stethoscopes of which we were cognisant. Many besides Drs. Hutchinson and Balbirnie may have used instruments either *exactly* similar, or bearing a more or less general resemblance to that noticed in your journal; but such not having, so far as we know, been published, we were perhaps not unnaturally ignorant of their existence. While recognising with your correspondents the advantages of the instrument, our experience of its use has caused us to attach such importance to the construction of the ear-peg as to consider it a distinctive feature. Let us hope that this form of stethoscope, having now been brought into more general notice, may retain its place, and that others may in practice corroborate the encomiums bestowed upon it by your correspondents. I am, Sir, yours obediently,
Canonbury, N., Nov. 9th, 1875. ALEXANDER MORISON, M.B.

Mr. John Snell, (Bacup.)—Several cases of the kind have been published in THE LANCET from time to time: e. g., in the number for Jan. 25th, 1873, the case of Hadaway *v.* Bournstone, at the Bloomsbury County Court; another in that of March 6th, 1875, page 360—a case at the Marylebone County Court, in which Mr. Serjeant Wheeler gave judgment for the plaintiff.

WARM SWIMMING BATHS.

To the Editor of THE LANCET.

SIR,—In your issue of the 6th inst., Bath is spoken of as possessing the only warm swimming bath. I have frequently bathed at Brighton in Brill's Circular Swimming Bath, the water of which is kept always at the summer temperature of the ocean. In winter it may be legitimately termed a warm or tepid bath, and must be superior to Bath in being *sea* water.

Yours faithfully,
November 10th, 1875. GEO. DELVES.

CASE OF TRAUMATIC GANGRENE OF RIGHT ARM; AMPUTATION AT THE SHOULDER-JOINT; RECOVERY.

To the Editor of THE LANCET.

SIR,—The following case is, I think, sufficiently interesting to have a place in your columns.

George B——, an agricultural labourer, of the parish of Down Ampney, Wilts, a fine muscular man, aged thirty, nearly six feet high, and twelve stone in weight, was engaged on Aug. 26th, 1875, in a large barn, in which machinery worked by steam power was in motion, when, somewhat out of bravado, he volunteered to put the strap on the wheel, which was twelve feet from the floor, connected with the chaff-cutting machine, and to do so he had to ascend a ladder that was resting against a beam of the roof which spanned the building, and being anything but an adept at the work, he leaned so far over the driving shaft, which crossed the said beam at right angles, that the left skirt of his jacket, or, to use his own phraseology, his slop, was caught by a projecting nut, so that he was very quickly wound up, and after revolving several times until the whole of his clothes were literally torn to rags, he was thrown diagonally across the barn on to a heap of straw which had been providentially placed there.

The man, though conscious, feeling very faint and exhausted, stimulants were administered to him, and in the meantime Mr. Langley, surgeon, of Cricklade, was sent for. He had the patient removed at once to his own home, which was about a quarter of a mile from the scene of the accident, and on examination found fracture of the left humerus, and some loss of sensibility and numbness in the right hand and forearm, which led to the opinion that the brachial plexus and probably the vessels had sustained serious injury; but the tumefaction around both shoulders was already so great as to render it very difficult to detect the exact nature of the injuries sustained. He was given a full dose of sedative solution of opium, cooling lotion applied to the left arm, and the right hand and forearm were enveloped in cotton-wool.

On the 29th the man was transferred as a pauper patient to Mr. Cornwall, F.R.C.S., of Fairford. There was now total loss of sensibility and motion up to the elbow; the part felt quite cold and clammy, and there was extensive purplish discoloration over the extensor surface. The shoulder was still very much swollen and painful, and, though no fracture nor displacement could be detected, there was evidence of the whole of the structures in the axilla and around the shoulder having undergone extreme strangulation before his clothes, which were made of very coarse and strong material, gave way. My own opinion was that both nerves and vessels were implicated, and that the latter were in all probability occluded by the torsion or twisting to which they had been subjected. He was ordered a fair allowance of wine, stout, beef-tea, &c., and continued the sedative dose at bed-time, which he much craved for.

Mr. Cornwall and myself visited the man alternately, and we very quickly found unmistakable proof of the death of the part, vesications arising, and other cadaverous changes taking place. The mortification continued to extend up the arm until the 6th September, when a distinct line of demarcation was visible about an inch above the insertion of the deltoid externally, but internally it reached the very apex of the axilla. The limb now presented a most loathsome appearance, for maggots were preying upon the poor dead member. Asking the man on one occasion how he was going on, he replied rather humorously that "he should feel better if he had not so much livestock in the bed."

At this stage I was strongly in favour of amputation; but it was feared that he was not in a position to bear it, and that even if he did not die under the operation he would in all probability have sloughing in the wound afterwards. However, as he lived on, and his condition, to say the least, became no worse, we decided at last to remove the limb; and on Sept. 13th, chloroform having been administered, and Mr. Langley compressing the subclavian artery and Mr. Cornwall having charge of the limb, I performed amputation at the shoulder-joint. Cutting from without inwards, I dissected up the integuments for nearly three inches, cut obliquely through the deltoid, separated the attachments of the muscles from the tuberosity, opened the capsule, threw out the head of the bone, and passing the knife behind it, I had merely to cut through the parts beneath; for the gangrene extended so high that no internal flap whatever could be obtained. The hæmorrhage on dividing the vessels being most profuse, I immediately grasped the axillary artery between my thumb and forefinger, and Mr. Langley placed a ligature around it. Unfortunately this slipped; but I again laid hold of it, and this time pulling it well forwards, and separating it from its close connexions, it was effectually secured. We then tied three other arteries which bled freely. By this time the poor fellow was wellnigh moribund; but by discontinuing the chloroform, and giving him brandy *ad libitum*, he was somewhat restored. The flap, which was not large enough to cover half the wound, was retained *in situ* by sutures very loosely applied, and the part covered with wet lint. Fearing secondary hæmorrhage, I remained with him for eight hours, and before leaving gave him a draught containing half a drachm of sedative solution of opium (Battley's).

On visiting him early the following morning, we found there had been no further hæmorrhage, that he had slept comfortably, and had taken a fair allowance of wine and beef-tea, and that the bowels and bladder had both been relieved.

I regret that notes of the case were not taken, as from memory I am unable to detail his state from day to day; but suffice it to say that he progressed uninterruptedly towards recovery, and the rapidity with which granulation proceeded, after the first few days, was very astonishing.

On Oct. 13th I removed the last ligature, and by the end of the month the wound had completely healed. The dressings throughout were of the most simple nature, our chief object being to keep the wound as healthy as possible. Doubtless the good hygienic conditions by which he was surrounded, and his own cheerful and sanguine disposition, influenced very greatly his recovery.

The injury to the left arm subsequently proved to be very serious, the fracture being comminuted, and extending into the elbow-joint. Union is now taking place; but I fear there will always be more or less impairment of motion.

Our thanks are due to Mr. Langley for his kind assistance at the operation, and the man's wife deserves great praise for the very excellent way in which she carried out our instructions, and attending to him with all the care and judgment of an experienced nurse.

I remain, Sir, yours truly,
Fairford, November, 1875. H. W. FURNIVALL, M.R.C.S. Eng., &c.

HOSPITAL VENTILATION.

Fraser's Magazine for the current month contains an article on the "Ventilation of Hospitals," which, without adding anything to what is already known, or attempting to treat the subject elaborately and upon a scientific basis, will, nevertheless, do good by diffusing information about the principles and general facts of hospital ventilation among subscribers to these institutions. In dealing with his subject, the writer draws largely upon Mr. Erichsen's excellent lectures on Hospitalism, which first appeared in the pages of THE LANCET, and upon the works of Reid, Parkes, Guy, Wilson, and others, with those of Miss Nightingale and Miss Florence S. Lees.

Birkenhead.—Our correspondent should apply to Messrs. Churchill.

A WASHING MACHINE.

To the Editor of THE LANCET.

SIR,—I send you a short description of a washing machine, recently invented for the purpose of washing the "cotton-waste" used for machinery, but so well adapted for cleansing all kinds of infected clothing that I venture to think that it should find a place in every hospital, workhouse, and public disinfecting establishment. The principle is simple, and the work so well performed that even the cotton-waste—a substance hitherto almost uncleansable, except by a process destructive to the fabric—is so perfectly freed from oil and starchy matters that its quality is actually improved and rendered available for the finest work.

The machine is the invention of Mr. W. Kirton, of Nottingham, where it may be seen in daily operation. It consists of a strong cast-iron steam-tight case, in which revolves a wire cage to contain the articles to be washed. This cage is divided longitudinally into compartments by perforated partitions. Superheated steam, boiling water, or cold water can be introduced into the apparatus by pipes communicating with the interior through the hollow axis which rotates the cage. These pipes are so perforated that the steam or water is delivered upon every part of the fabric to be operated on. Thus, supposing the machine to be filled with sheets, blankets, or other articles, the lid is clamped down, and superheated steam is forced in from the engine boiler, afterwards hot water is introduced from the same source, and the steam being still admitted, the contents are well boiled, whilst the cage is made to revolve rapidly. By opening a stop-cock, the dirty water is drawn off (being completely expelled by the action of the steam), and cold water is introduced. The vacuum thus produced, together with the centrifugal action of the revolving cage, effectually rinses the clothing.

In the case of greasy materials, the inventor has prepared an ammoniacal soap, which he uses also for the purpose of washing ordinary household linen &c., and certainly the difference between specimens of articles washed by this machine and those "got up" by the washerwoman is most striking.

During a recent visit to Nottingham, Mr. Kirton showed me one of these machines, set up in an ordinary sized washhouse attached to his private residence. It was worked by a one-horse power steam-engine, and fully illustrated the practical advantages it possesses over the common appliances seen even in our best equipped hospital laundries.

This description is necessarily imperfect; but enough has been said to show the various adaptations to which the apparatus may be subjected for the purpose of disinfecting articles of clothing.

Yours sincerely,

Lincoln, November, 1875. G. M. LOWE, M.D.

Curious.—It is now very rarely bestowed, and, in fact, the practice has fallen into desuetude and almost into oblivion.

Mr. J. McInnes is thanked for his offer, which, however, we regret we cannot accept.

"GILEAH."

To the Editor of THE LANCET.

SIR,—In *The Times* of Tuesday last, under the heading "Tragedy on Board Ship," are reported the murderous actions of a seaman, named "Noan," while on a voyage from Hong-Kong to Bangkok. The explanation of these deeds is given by the captain as follows:—"The man Noan, by whom the tragedy was committed, was suffering from a disease known among the Malays and Siamese as 'gileah' or 'amocque.' It takes the form of ringworm, and is attended in *every* case by madness of more or less severity."

As everything contributing to enlightenment on the pathology of insanity is of importance, especially the somewhat vexed question of co-existence of skin disease with it, perhaps some of your readers who may have observed the disease in question may be able to give a description of it. It has not been my own fortune to meet with the association, although I have seen much of skin disease, including ringworm, among Eastern people.

I am, Sir, yours faithfully,
JAMES ADAMS, M.D.,
Medical Superintendent.

Metropolitan District Asylum, Caterham, Nov. 10th, 1875.

UNQUALIFIED PRACTICE AND QUALIFIED PRACTITIONERS.

To the Editor of THE LANCET.

SIR,—As you say the case of "One whose Qualifications afford no Protection" is a very bad one, I think I can give you a case which equals it in many particulars.

One of the medical men in my neighbourhood habitually employs an unqualified assistant, who does almost all his parish work, vaccinates for a public appointment without his principal in many cases *seeing the children* at all, and to my knowledge attended five midwifery cases in one week. In many cases the assistant has attended long illnesses, and the patient has been seen once or twice by the principal before death, and the usual certificate given.

As your correspondent so justly remarks, the clubs (which are also greatly attended by the unqualified assistant) are ruled by the few, with whom the medical man is careful to keep on good terms, and attend well; whilst in many cases the others have to send twice or three times before being seen.

Certainly the profession cannot hope to be defended from quacks whilst the (in almost all cases) old members behave so shamefully themselves.

I remain, Sir, yours &c.,

November, 1875. ANOTHER WHO IS QUALIFIED.

"MEN OF THE WORLD" v. "SCIENTIFIC SPECIALISTS."

THE following passages from an article on the "Report of the Poor-law Board" in the last number of the *Saturday Review* deserve attention:—

> "There is so much indolence to be surmounted, there are so many private interests to be overridden, that there is not much chance that Parliament will take so unpopular a task in hand until something like an intelligent opinion can be created out of doors. The Reports of the Local Government Board Inspectors would supply the materials out of which this opinion would have to be constructed. They are laymen, and therefore not likely to take a purely medical view of the facts presented to them. Their estimate of the acts of the several sanitary authorities will be the estimate of *men of the world*, not of *scientific specialists*, and it will for that very reason be the better calculated to impress men of the world. If it were desired to raise the sanitary condition of the country to an ideal pitch of perfection, it would no doubt be expedient to go to the doctors for suggestions; but since all that we can at present aim at is to make that condition conform to common-sense rules, which are conceded in theory almost as universally as they are violated in practice, laymen answer the purpose better. Yet it is the Reports of the laymen that are carefully kept back from the public."

When a generally intelligent and well-informed dogmatist is so carried away by his prejudices that his dicta become ludicrous, it is sometimes sufficient for the purpose of recalling him to consciousness that his argument should be transformed into a *reductio ad absurdum*. May we be permitted to apply that treatment to the reasoning of the *Saturday Review?* The change of words required is singularly slight.

> "If it were desired to make the country perfectly healthy, it would no doubt be expedient to go to persons who have devoted their lives to the study of the causes, the prevention, and the cure of unhealthiness for suggestions; but since all that we can at present aim at is to make it moderately healthy, the advice of persons who have not made a special study of health or disease, and who are only 'men of the world,' will answer the purpose better."

The same method of reasoning might be applied to other matters. For example:—

> "If it were desired to produce an article likely to place the needs of the sanitary situation before the public with a fidelity wholly free from prejudice, and rising to a pitch of perfection, it would no doubt be desirable to go to somebody who understood the subject for suggestions; but since all that we can at present aim at is to give such a version of the case as shall magnify the pretensions of laymen and depreciate the services of the doctors, the assistance of a layman will, of course, answer the purpose better."

It is impossible not to perceive that the *Saturday Review* has hit on an excellent expedient to secure the end apparently in view.

A CAUTION.

To the Editor of THE LANCET.

SIR,—It is well that through the columns of your widely circulating journal the profession should learn of the latest novelty in pushing the notoriety of those unblushing pretenders who feed on the weakness and gullibility of suffering humanity, for which purpose you will kindly admit the following details, the veracity of which is guaranteed by the enclosure of the names of all the parties concerned, though it is not needed to publish them.

A lady, suffering from cancer, was ordered to —— for change, and desired to proceed by the easiest mode of conveyance. Her sister proceeded to the chief railway station to engage an invalid carriage, and saw the official in charge of such arrangements, who, although not prepared yet with slinging hammocks, promised to make the most comfortable disposition of the means at his command. Then requiring to know the nature of the disease of the sufferer for whom it was necessary to engage this mode of transit, and being told that it was for a lady affected with cancer, said, "Oh, we have a Swiss doctor here who cures cancers and consumptions. He cured one of our porters, who was turned out of the Consumption Hospital as incurable." The lady, on this recommendation, requested the address of this "Swiss doctor," and his services were obtained for her poor sister, it is idle to say, with the usual result of a large expenditure of money, a fearful increase of suffering, and, worst of all, the painful frustration of hopes buoyed up by cruel deceit and fraudulent misrepresentations.

Surely no railway board would sanction such an unwarrantable interference with passengers by their trains from any of their officials, and the public ought to be protected from imposition reaching them in such an insidious and dangerous form. That the "station master" was justified in seeking the knowledge of the malady, as to its nature, whether contagious or not, is true; but to require information for the purpose of pushing the services of any irregular practitioner of the healing art is too great a strain on the credulity of the age to impute the motive purely to benevolence.

I am, Sir, yours truly,

November, 1875. ARGUS.

Mr. Clement E. Priestley, (Ely.)—The medical officer of health has no privilege of entry under the circumstances stated, except by permission of the head of the family, and such permission does not exonerate him from the courtesies due to the medical man in attendance. In this case the medical officer of health should first have communicated with the medical attendant.

TREATMENT OF INCONTINENCE OF URINE.

To the Editor of THE LANCET.

SIR,—In THE LANCET for January 23rd, 1875, appeared a communication from me, requesting suggestions as to the treatment of a long-standing case of incontinence of urine. In reply to the numerous suggestions that were kindly offered through the medium of your journal, I beg to state that I treated the case with five-minim doses of tincture of belladonna three times a day, following out the suggestion of Dr. James Sawyer. The treatment was continued for six weeks, with very marked improvement, and at the present time the patient is almost entirely free from this very harassing complaint. The successful treatment of the case with belladonna is, I think, worthy to be noted, as cases of this kind are not unfrequent.

Very truly yours,

London, Nov. 11th, 1875. B.

The "Differential" Stethoscope.

To the Editor of The Lancet.

Sir,—I observed in the advertising columns of last week's Lancet Mr. Millikin's advertisement of a so-called "differential stethoscope." With reference to this advertisement, I beg to say that the instrument in question was one of my earliest and very imperfect attempts at the production of a biaural stethoscope with head-spring, and was obtained, as I have discovered to-day, by Mr. Millikin in May last from the instrument-maker who was working out my idea. Doubtless without any harm being intended by either of the parties concerned, this is an infringement of my invention of a head-spring stethoscope, at present being introduced by the Messrs. Arnold, of West Smithfield.

Trusting you will allow this letter to appear, along with the enclosed letter from Dr. Herbert Davies relative to the same subject,

I am, Sir, yours truly,
R. Harvey Hilliard, M.D.

Belgrave-terrace, Upper Holloway, N., Nov. 9th, 1875.

23, Finsbury-square, E.C., Nov. 9th, 1875.

Dear Dr. Hilliard,—You kindly gave me about two years ago a very convenient and ingenious double stethoscope, provided with a head-spring, which you had invented. As a similar instrument has lately appeared, I think it is only due to you that I should state the fact above mentioned.

Believe me, yours very truly,
Herbert Davies.

P.S.—You may, of course, make use of this note as you think fit.

Typhoid and Distemper.

To the Editor of The Lancet.

Sir,—The evidence presented by "H. H." respecting the connexion between "distemper" in the dog and typhoid in the human being tends to confirm an observation that I made eight or nine months ago.

I was attending a batch of typhoid cases of a severe type, to account for which I could not at first discover any cause; but a short time afterwards I was called to attend an eccentric woman (residing in the midst of the infected neighbourhood), also suffering from typhoid. She had in the house six or eight canine pets, all of which seemed to be suffering from some form of distemper. It occurred to me that this might be the source from which these typhoid patients were infected. I caused all the dogs to be destroyed, but unfortunately no post-mortem examination was made. No fresh cases in that vicinity have since come to my knowledge.

Manchester, Nov. 10th, 1875. C. L. Smithard, M.R.C.S. Eng.

Communications not noticed in the current number will receive attention in our issue of the ensuing week.

Communications, Letters, &c., have been received from—Dr. G. Johnson, London; Prof. Maclean, Netley; Dr. C. Theodore Williams, London; Prof. Macleod, Glasgow; Mr. Garland, Yeovil; Mr. Chambers, Chester; Dr. B. Foster, Birmingham; Mr. Saunders, South Molton; Dr. King, Hull; Mr. Robinson, Dorchester; Mr. Mitchinson, London; Dr. Bond, Brinklow; Dr. Senftleben; Dr. Purvis, Mainhouse; Rev. J. A. Hatchard, St. Leonard's; Mr. Bell, Uppingham; Mr. Deschamps, London; Dr. Daly, Dalston; Mr. Layton, Islington; Dr. Mercer, Beverley; Dr. Carpenter, London; Mr. Smart, Brighton; Dr. Donald, Ceylon; Mr. Reed, Stafford; Mr. Hardman, Blackpool; Dr. Wilson, Greenock; Mr. Thompson, Spennymoor; Mr. Furnivall, Fairford; Dr. Gould, London; Mr. Thomas, London; Messrs. Medical Diary for the ensuing Week.

Monday, Nov. 15.

Royal London Ophthalmic Hospital, Moorfields.—Operations, 10½ a.m. each day, and at the same hour.

Royal Westminster Ophthalmic Hospital.—Operations, 1½ p.m. each day, and at the same hour.

St. Mark's Hospital.—Operations, 9 a.m. and 2 p.m.

Metropolitan Free Hospital.—Operations, 2 p.m.

Medical Society of London.—8½ p.m. The Discussion on the "Case of Excision of the Astragalus," shown by Mr. Watson on Monday last. — A paper by Dr. Drysdale: Subject, "For and against Animal Vaccination."

Tuesday, Nov. 16.

Guy's Hospital.—Operations, 1½ p.m., and on Friday at the same hour.

Westminster Hospital.—Operations, 2 p.m.

National Orthopædic Hospital.—Operations, 2 p.m.

West London Hospital.—Operations, 3 p.m.

Pathological Society of London.—8½ p.m. The following Specimens will be exhibited:—Fractured Bones of Gorilla; Rickets in Pheasants; Distended Diverticula of Intestine; Pulmonary Embolism; Tubercle of Pancreas; Tumour of Jaw; Tubercular Lupus of Tongue; Fatty Tumour of Male Breast; Hydatid in Heart; Elio-sarcoma of Brain; Larynx after Tracheotomy; Dilatation of Bile Ducts; Aneurism of Aorta; Obliteration of Superior Cava; Ulceration of Duodenum; Congenital Malformation of Œsophagus; Syphilitic Growth of Cerebral Sinuses; Disease of Pulmonary and Tricuspid Valve; Hæmorrhagic Periostitis; Elioma of Brain; Fatty Tumour of Spinal Cord; Congenital Deficiency of Common Bile Duct; &c. &c.

Wednesday, Nov. 17.

Middlesex Hospital.—Operations, 1 p.m.

St. Mary's Hospital.—Operations, 1¼ p.m.

St. Bartholomew's Hospital.—Operations, 1½ p.m., and on Saturday at the same hour.

St. Thomas's Hospital.—Operations, 1½ p.m., and on Saturday at the same hour.

King's College Hospital.—Operations, 2 p.m., and on Saturday at 1½ p.m.

Great Northern Hospital.—Operations, 2 p.m.

University College Hospital.—Operations, 2 p.m., and on Saturday at the same hour.

London Hospital.—Operations, 2 p.m.

Samaritan Free Hospital for Women and Children.—Operations, 2½ p.m.

Thursday, Nov. 18.

St. George's Hospital.—Operations, 1 p.m.

Royal Orthopædic Hospital.—Operations, 2 p.m.

Central London Ophthalmic Hospital.—Operations, 2 p.m., and on Friday at the same hour.

Harveian Society.—8 p.m. Dr. J. E. Pollock, "On certain Varieties of Heart Disease with reference to Prognosis and Treatment."

Friday, Nov. 19.

St. George's Hospital.—Ophthalmic Operations, 1¼ p.m.

Royal South London Ophthalmic Hospital.—Operations, 2 p.m.

Saturday, Nov. 20.

Royal Free Hospital.—Operations, 2 p.m.

Charing-cross Hospital.—Operations, 2 p.m.

Introductory Address
TO
A COURSE OF LECTURES
ON THE
PRINCIPLES AND PRACTICE OF SURGERY.

Delivered on the 5th of October, 1875,

BY THOMAS BRYANT, F.R.C.S.,
SURGEON TO, AND LECTURER ON SURGERY AT, GUY'S HOSPITAL.

GENTLEMEN,—It is with unfeigned pleasure that I to-day appear in this theatre as one of your lecturers on surgery, and, as a duty, have to unfold before you the scroll upon which has been written by the skilled hands of the master minds who have preceded me—many in this place—the principles and practice of the divine art of surgery.

I acknowledge with satisfaction that I am entirely indebted to this position, through the treasurer, to the kind action of my colleagues; and freely admit that this fact added no little to the pleasure I felt in accepting an honour that in itself amply satisfies my highest surgical ambition; for I know of no prouder position than that bestowed upon us by our fellow-workers. It is true that the pleasure and honour of the position are a little dulled by the responsibilities with which it is surrounded and the natural anxiety that I confess to feel as to my capabilities of doing adequate justice to so great a subject. But the kind reception you have just given me, and the confidence reposed in me by those whose confidence I value, will do much to lighten the load I have undertaken to bear, and to assure me that any shortcomings on my part in the mode of my teaching will by you be considerately dealt with, if I perform what I now undertake to do—to give you good advice as to the nature and treatment of such surgical subjects as it will be my privilege to bring before you.

In the delivery of these lectures I shall ever bear in mind that you have come here to learn how to practise your profession, and, as a consequence, I shall regard it as my duty to teach you how you ought to act under different emergencies—how you are to treat certain diseases; and in doing this it will be my aim to give you principles of practice rather than details—to point out to you the road you are to walk in rather than the manner in which you are to walk; for in our profession a knowledge of principles is the only sure and fruitful source of its progress, and the knowledge that a man can use is the only real knowledge that is available for its practice. I shall therefore suppress all inclination to enter with you into argumentative discussions or abstract questions, although I shall not forget to point out lines of thought with which you may profitably occupy your leisure hours, or upon which you may exercise your speculative and reasoning faculties; but I shall ask you to do this only when you have learnt what I shall hope to teach.

My teaching will consequently be as practical as I can make it—using the word practical in its fullest sense, rather than in its empirical; for I shall base it upon the scientific knowledge of our profession, upon the broad principles of general pathology,—the pathological aspect of disease being, however, subservient to the clinical, which has reference to the peculiarity or special constitution of the individual patient. For example, before I point out to you the special treatment of *wounds*, I shall first describe how repair takes place in the different tissues, and I shall do this in order that you may know how best to help natural processes, and how not to interfere with natural repair. In the treatment of *hæmorrhage*, before I describe the different means the surgeon has at his command for its control, I shall show you how by natural hæmostatics hæmorrhage is arrested; and I shall do this in order that you may understand the principles upon which your practice should be based, and that you may select the means that utilise to the utmost natural processes. In the treatment of *aneurisms*, before I go into the details that are so necessary for their cure, I shall show you how a natural cure may occur; for that surgeon will be most successful in his means who understands the most fully the physiological processes employed by Nature for this end, and is the best able to turn them to account. In the treatment of *dislocations*, before I describe to you the best methods for their reduction, I shall point out what it is that prevents the restoration of a displaced bone to its normal position, in order that you may recognise the sources of difficulty that you are likely to meet with in their treatment, and why it is that bones, when displaced, are not always readily reduced. In the treatment of *fracture*, I shall first show how repair takes place, and how it may be interfered with, in order that you may know how best to utilise the processes you want to encourage, and how to avoid what may retard or neutralise their action.

In short, before I tell you how you are to deal practically with, or treat, the different accidents to which the human body is exposed, I shall point out how you may best utilise natural processes for their repair, and how you may avoid interfering with them; for I would wish to impress upon you all, in this the very beginning of a course of lectures upon the Practice of Surgery, the wisdom of your accepting as a living and abiding principle of action, that should be with you in all cases and under all circumstances, and that should influence you in the treatment of all injuries and of most diseases—I mean "an unbounded faith in the restorative power of natural processes." I mean, however, no blind faith that is to lead you into a negative and idle practice—no faith that will support, even to the slightest degree, a do-nothing and blindly expectant course of treatment. But I mean a faith that is based upon a sound knowledge of the processes that Nature adopts in the repair of injuries, even the most severe—a faith that leads you to inquire so closely into the action of these natural processes as to teach you how you may best remove such obstacles as may interfere with their steady evolution—a faith that will teach you to use to the full the means you have at hand in natural processes for the repair of injuries, and that will prevent you from doing anything that is likely to interfere with their steady and beneficent action. For, gentlemen, in the treatment of all injuries, let the surgeon put aside altogether every idea of his being able to cure the wound; let him accept cheerfully and gratefully a more humble position, and look upon himself as Nature's handmaid; let him feel also that by so doing he is well fulfilling his high mission. Let him do what Nature unassisted cannot do—replace displaced parts, and by mechanical contrivances keep them in position. Let him remove all foreign bodies that must irritate, and take away all hindrances to natural repair, and so apply his dressings and regulate the surroundings of a case that no harmful influence can take effect. *Let him then leave the case alone*, guarding it with a watchful eye ever open to suggest the removal of what may interfere with natural repair, or the application of what may prove a help towards the attainment of the desired end. When absolute rest is one of the essential elements of success, let absolute rest be afforded, and when movement is called for, let such be enforced; for let the surgeon feel that in accidental surgery, when he has replaced injured parts as well as he can in the position in which they were before the injury, and by mechanical appliances has so fixed them that no movement or outside influence can readily interrupt the natural process of repair—when he has removed everything that is likely to interfere with the steady evolution of the process, he will understand in all its fulness *the evil of meddlesome practice, of meddlesome surgery*, and be ready to recognise the truth of the maxim I now wish to impress upon you, that under all circumstances and in the treatment of every case, even the most simple, the surgeon should, before he interferes, to use a legal phrase, show cause why he should do so; for I would have you bear in mind that every act in surgery, as in every-day life, should be based upon a principle and have a definite object; in the treatment of any surgical case, however simple, no step should be taken, no interference sanctioned, unless with the view of carrying out some reasonable scheme, or the attainment of some definite end, and unless such a view is before the surgeon I hold that it is his bounden duty under all circumstances to stay his hand, and stand by, and in an expectant state of mind to watch the progress of the case until the time for action has arrived. For if the surgeon be not sure that he can do good, let him be sure that he does no evil. If he is not clear that the time for action has arrived, let him be clear that the time for interference has not. Let him know that meddlesome surgery is as injurious as meddlesome midwifery, and meddlesome statesmanship, and let him learn, when disposed to interfere without a definite reason, from the great politician and captain who governed this country so wisely and so well, and ask himself the question—*Why cannot he leave the matter alone?* The onus of action must always rest upon the back of the surgeon. Let him see that he carries it with judgment, and let him know that in the practice of surgery, as in other things, a masterly inactivity is often a valuable policy; for to do nothing is often a wise treatment, and by knowing how to wait a great deal more is often effected than by interference. A policy of inaction may try a man's energy, and tax his power of self-restraint; its adoption may also demand as much thought as, and possibly more wisdom and effort, than the greatest activity. But true wisdom should teach us as much what not to do as what to do, and in the practice of surgery inaction is far better than action when to act means simply to err.

Let me, however, impress upon you the wisdom of acting decidedly and boldly when action is called for; let no vacillation spoil your practice; let no half measures be employed that carry out but in part the principle or practice you have been led to regard as the right one to follow, and never hesitate to carry out to the full the legitimate conclusions of your own unbiased judgment. In fact, as an honest man, give your whole mind to the case before you; weigh all its points, and estimate their value, and having *judiciously* come to a conclusion as to its nature and requirements, *judicially* proceed to carry out the decision of your own judgment: do this also with a wise boldness, with a courage tempered with the responsibility of your act.

Let me now turn to the subject of *operative surgery*, and see how far the remarks I have just made are applicable to it. Let me ask if faith in the restorative power of natural processes is still to be your guiding influence? and if, in the treatment of injuries and disease, the surgeon, before he acts, is always to show cause why he should interfere, such a rule of practice in operative surgery is still to be enforced? Let me inquire whether the evil influence of a meddlesome practice has diminished, or the soundness of a policy of inaction in certain circumstances lessened. And, lastly, let me ask if a wise caution in deciding on interference is of less moment, or a discreet boldness in action of less account? Gentlemen, I must tell you that all those principles of action when applied to operative surgery are to be read with double emphasis, and I must ask you to keep them before you as your guiding rules of practice; for, I can assure you, if they are of value in the non-operative development of practice, they are of infinitely greater value in the operative; and that unless you have them by you as guiding principles by which all your thoughts and acts are to be influenced, you will be too apt to fall into bad ways, and, as surgeons, fail to do justice to your patients and to yourselves, or to bring credit to your school. It is true, when a limb has been crushed or irreparably injured, when a part has been attacked by a disease which clinical experience has taught the surgeon to be incurable, that faith in Nature's restorative powers may be misplaced. But when art has stepped in and taken away what Nature unassisted is incompetent to deal with; when the surgeon, as Nature's handmaid, has given a helping hand to natural processes, and has taken away by artificial means what by natural means could neither be restored to usefulness nor cast off,—this faith in the restorative power of Nature may be practically relied upon; for the surgeon has only to adjust the parts that have been disturbed by his operation and to leave them alone, to protect them from external injury, and guard them against all outside influences that may interfere with the healing process. He has but to leave them to natural processes for repair, as in the simplest wound.

I must ask you, however, to bear in mind that, *in deciding upon the performance of an operation*, much thought and care are called for; and let me beg of you, as surgeons, always to feel that you do this under a heavy responsibility, for in the smallest operation there is a risk, and no risk to life should be run without a definite reason. Never look at the case from a purely surgical point of view, and be still more careful that you do not regard it from your own standpoint. Look at it from your patient's point of view alone, and simply ask yourself if it is to his interest and for his advantage that it should be undertaken. For example, you have a patient under your care with a certain disease, and if you regard this disease purely from a surgical point of view you may say at once that it would be a good case for such an operation, and as that poor professional thing—a mere operator—you may be tempted to do it. You regard the case from your own standpoint, and may be encouraged to interfere from the pleasure the performance of the operation may afford you, the benefit its performance may do you in the eyes of your neighbours, or the whip it may perhaps give you over a brother and possibly a rival practitioner. In the given case one or all of these influences may take effect, and urge you to interfere. You look upon the case from your patient's point of view, and may possibly see that the operation is not a necessity, and that, if *expedient*, it is so to a very limited degree; or in weighing the matter more closely, purely with your patient's interest at heart, you may decide that the operation is neither a necessity nor expedient; and, on still closer thought, you may come to the conclusion that if you were in your patient's position, with your knowledge of the case and all its risks, you would not have the operation performed. As a surgeon and a true man you will be influenced by these last considerations, you will decide against interference. The purely professional aspect of the case will be set aside with the purely personal. Your decision will be influenced by the necessities of the case as read in the light of your patient's interests, and that alone.

These arguments apply likewise with equal force *to the selection of the operation that is to be performed.* Your patient's good, and his alone, is to be considered. Let no fancy on your part for a certain operation tempt you to do more than the requirements of the case demand; let no personal preference for an operation influence your decision. Having decided that operative interference is called for, make it clear to your own mind what the necessities of the case demand, and having done this, so arrange your plans that you can carry them out in the simplest way and with the least risk to life. In short, do from necessity what the necessities of the case require, and do what you have to do in the simplest and safest way.

For example, if you have a case of stone in the bladder to deal with, it may be your duty to take it away, and if so, you are bound to do so by the simplest means and by the safest operation. If the accumulated experience of the profession tells you that the simplest and safest way is by a crushing operation, you are bound to do it if you have sufficient skill, and if you have not, you should pass the case over to another who has. And if by the same large experience you are told that a cutting operation is preferable, by the same principle it is your duty to see that it is carried out. No mere personal preference for, or personal success in, one or other of these operations ought to have the slightest influence upon you in guiding your decision; you are to consider your patient's interests, and his alone.

Again, you have a patient with disease of the foot involving some of the bones and smaller joints, and from the progress of the case it is clear that nature unassisted is incompetent to heal it. An operation is, therefore, called for, and you have to decide what that operation shall be. Is it to be one that is solely determined by the requirements of the case? Or is it to be one for which you personally have a fancy, or which your own limited experience—for all mere personal experience is comparatively limited—leads you to regard with favour? Gentlemen, you anticipate my answer, and know that I am about to tell you your decision should be influenced alone by the requirements of the case, and by nothing else. As a surgeon you are bound to take away the disease, but nothing more. You are neither to consider this operation nor that; no preference for a Hey's amputation, a Chopart's, a Pirogoff's, or a Syme's, is to have any weight with you. If by a Hey's amputation you can take away the disease, for the removal of which your interference is alone justifiable, no further sacrifice of parts should be entertained. If the disease be more extensive, and can only be removed by a Chopart's amputation, a Chopart's amputation is the one you ought to adopt. When nothing less than a Pirogoff's amputation will take away what requires removal, a Pirogoff's may be performed; and a Syme's amputation is only to be entertained when the disease is too extensive to permit of the Pirogoff's being carried out. And when none of these operations will effect what you want (the removal of the disease), an amputation above the ankle may be had recourse to, for, by the testimony of all surgeons, the major operation of amputation of the leg is alone justifiable when the minor operations upon the foot are inapplicable or have failed.

Gentlemen, this testimony against amputation is based upon a sound principle, and is universally admitted; and surely, by the unbiased or unprejudiced reason of all surgeons, the same arguments that apply to amputation of the leg should apply to each of the enumerated operations in their order of magnitude over the minor. The surgeon who would teach that amputation of a foot above the ankle should be performed for all diseases of the foot that require removal would rightly lay himself open to censure; but surely the surgeon who always performs a Syme's amputation when something far less serious would suffice—who shuts his eyes to the advantages of the minor operations, and consequently, from want of experience, fails to know them—is not quite free from blame. At any rate, gentlemen, do not you fall into such an error. Remember that, as surgeons, it is your duty to take away from the body only such parts as are irreparably injured or diseased, and nothing more; that in the surgery of the foot you are to do this by the minimum of interference; and that all the operations I have named in their order of severity are good when well applied.

From the surgery of the foot also learn the surgery of the body; or, rather, through the surgery of the foot learn the great principle that ought to influence you throughout all operative surgery. Learn to know that, as a duty, you are only to remove from the body what nature unassisted cannot cast off, and what, if left, will interfere with life or life's usefulness; and bear always in mind that you are to do this with the least risk to life, with the least sacrifice of parts, and with the least local disturbance.

When I tell you that the surgeon is always to operate with the least risk to life, you may think that I am repeating an axiom which needs no enforcement, and yet I would wish to bring the point before you if only to impress upon you the necessity of its observance; for as a surgeon I cannot honestly say that it is always acted upon with the closeness which it is due, nor with the strictness which the conviction of the sacredness of life ought to enforce. Gentlemen, as surgeons, always regard life as a sacred thing, and let it be your primary aim to preserve it or prolong it. When considering an operation this feeling should influence you much; indeed, without such a feeling no operation should be entertained. And let me add that it is a thought that will often simplify many of the questions that come before you; for if in any given case you have to select one of two operations, and by referring *to the experience of the profession* you find that one of the two operations you are considering is far more fatal in its effects than the other, the weight of evidence ought to go against it; at any rate the advantages to be gained by the more dangerous measure ought to be very great indeed to justify the surgeon in selecting it in preference to the one that has been shown by general experience to be the safer. For example, let me take a case of disease of the knee-joint in a young subject, say under twenty, and let me assume, for the sake of argument, that by the flux of time it has become clear that Nature, even when well and fully assisted by art, has proved herself incompetent to effect a cure by natural processes, and that the removal of the disease by some operative measure is called for. What is that operation to be? Is it to be excision or amputation? And I put this question to show you how necessary it is to consider the influence of age upon the results of an operation. To answer it you refer to the accumulated experience of many surgeons, not resting solely upon your own, and find that in amputation for chronic knee-joint disease in subjects under twenty, the mortality is not greater than 1 in 17 cases, and by a reference to the same general experience in excision, you find that it is at least 1 in 3½; the mortality of excision of the knee in young subjects being five times as great as that of amputation for chronic joint disease; or, in other words, we find that by amputation sixteen recoveries are to be secured with one death, whereas by excision the same number of recoveries can only be secured by five deaths, four lives being unnecessarily sacrificed to secure the advantages of excision to fifteen subjects. Now, let me ask you if the advantages afforded by the operation, even by the most successful cases of resection of the knee-joint, can in any way compensate for the unnecessary loss of so many human lives; and if the advantages of excision can possibly be so great as in any way to justify the surgeon in performing the operation as a rule of practice? With the sanctity of life prominently before me, and with the feeling that to save life is our highest duty, and to add to life's usefulness the next, I have no hesitation in saying that excision of the knee-joint, as a rule of practice in young patients, ought not to be adopted. That it is justifiable in exceptional cases in young life, and as a more common rule of practice in subjects of a greater age, is doubtless true; for by the same arguments that I have adduced against the operation in young subjects, the practice may be justified in the older in exceptional cases. But what I wish to illustrate by this question of operation is a principle: it is to show you that you are to consider the life of the patient before other things, and that in comparison with it all other points sink into insignificance. I confess, when a surgeon shows me with a smile of satisfaction a successful case of excision of the knee in a child or subject under twenty, I see behind that smile the ugly fact that, to gain one result in which he glories—if his experience has been extensive,—many inglorious results have taken place. I feel, also, that the success has been bought at too high a price, and that it ought not to be encouraged.

When I lose my judgment and become an enthusiast, when I look to my own experience alone and ignore the accumulated experience of others, pin my faith to a system which has to be established, and, in my enthusiasm for a theory, presume to talk about controlling natural processes and guaranteeing a successful termination to any operation I may have the will to undertake, I shall doubtless teach you other things; but with the calm light of the past illuminating the present, with a mind still open to receive the facts which the experience of those who have preceded me have given, and a judgment not yet clouded by any strong personal bias for or against any theory or any practice, I am urged by a sense of duty to bring prominently before you the principle upon which I have enlarged and illustrated, and beg you, before anything else, to let the main object of all your surgery be the saving of life; and next to the saving or prolonging of life let it be your aim to add to life's usefulness. But take care that you do not this at the expense of the higher object; take care that in attempting the minor object you do not fail in the major; take care that in your anxiety to add to life's usefulness you do not sacrifice the life itself.

When considering the advisability of an operation upon an aged subject, consider well these points. Think twice, and even thrice, about performing an operation that is not a necessity to save life—that is not called for urgently by the danger the presence of the disease produces, or by the distress that it causes. Hesitate about performing any operation of expediency upon such a subject. For example, if anyone, man or woman, has a simple fatty or other tumour, the presence of which affects life but distantly, or is merely a discomfort or an inconvenience, do not touch it; for if you do, you do so at a risk to life which the necessities of the case do not warrant, although in a younger subject surgical interference would be justifiable. You meet with an old man who has a stone in his bladder, and the stone, beyond giving rise to mild symptoms of its presence, does not render life distressing or unendurable, and you have to decide upon the treatment of the case. What are you to do? I will tell you what you are not to do, and that is you are not to risk the man's life; you are not to perform any operation upon him that does this to any extent; you are not to cut the patient by lithotomy, nor are you to attempt to crush the stone if many operations are likely to be required. You would be justified only in interfering if you find the stone small, and if, on carefully weighing probabilities, not more than three sittings will be required. You are not, however, to do this if the man has soft and fat textures. If there are any indications of visceral mischief, such as lung trouble, particularly bronchial, liver derangement, or last, but not least, renal trouble; you had better leave the case to nature, and relieve symptoms by the many ways your art suggests, than by any act of yours endanger life. If you are not sure, as I said at an early part of this lecture, of doing good, be sure that you do no harm. The patient may die, but take care that he does not do so at the surgeon's hands.

By the same argument you will hesitate about performing any operation, that is not an urgent necessity to save life, upon any subject who has exhausted his powers by drink, or who is either a drunkard or an habitual spirit-drinker. Hesitate also about interfering with any great eater. But above all things hesitate about performing any operation that is not a necessity upon the subject of Bright's disease.

Remember, also, that operative surgery, although an important part, is only a part of surgery; and recognise the fact that the higher duties of the surgeon are to be found outside the operative department and away from the operating table. But, at the same time, bear in mind, when the surgeon, through his higher faculties, comes to the conclusion that an operation is a necessity to save life, or is justifiable to prolong it or to render life more valuable, it is his bounden duty so to have educated his manual powers, so to have studied the mechanical part of his art and the necessities of the case he has to deal with, as to be able to carry out with all the skill of which the living matter he is dealing with is worthy the dictates of his own judgment; and let him be sure, if success does not crown his efforts, that failure can in no way be attributed to any want of ordinary skill, any want of care, or any want of preparation. For the ultimate result of an operation rests, without a shadow of doubt, upon the right execution of each step in it; and when each step has been efficiently performed the surgeon's duty has been fulfilled. But remember that a failure in any one of the steps of an operation, from the very beginning of the case up to the final dressing of the wound, as a rule, means failure in the whole, and that a want of attention to what might appear to be a trivial matter may spoil what would otherwise have been a brilliant success; for success in operative surgery rests as much upon the right execution of so-called small points as of the large, and that surgeon is the most successful who, with the main object of his operation in view, looks most into details. By the operating surgeon, nothing that tends towards success should be looked upon as trivial—nothing so small as to be beneath his notice.

Gentlemen, I must now close my lecture, and I will do so by asking you to carry away the principles I have attempted to enunciate, and to accept them as guides in your professional career. Ponder over them at your leisure, and so make them your own; take them into your minds and mentally digest them, so that they may become part and parcel of your nature, and find expression in the daily acts of your professional life. Bear in mind that all wounds—accidentally received or surgically produced—are healed by natural processes, and that all the surgeon can do in their treatment is to remove obstacles to natural repair, place wounded parts in the position in which natural repair is the best effected, and stimulate the process. Have unbounded faith in the restorative power of natural processes. Before you interfere in any case with things as you find them, always feel that the onus of interference rests with you, and that unless you can show good cause to your own mind why you should do so, you had better leave matters alone. Have a horror of meddlesome surgery, and a great respect for a do-nothing practice when no indications for doing, or for doing good, present themselves; but remember that by doing nothing judiciously you often do more good than by action, and that to know how to wait is a great power. When action is called for, act boldly and with decision, and let no vacillation spoil the practice your own honest judgment has pronounced to be right. Act in all things under a deep sense of the responsibility of your actions, and remember at all times that it is with a human life you are dealing.

In operative surgery let these feelings have their fullest influence, and in no case nor under any circumstances perform the simplest or the largest operation unadvisedly. Bear in mind that in the simplest operation there is a risk to life, and that under all circumstances that risk is to be recognised. Remember likewise that that risk is not to be run without a definite reason. Always recognise it yourselves, and see that it is made known to your patient or to his friends. Treat no operation as being absolutely free from danger, and never presume to guarantee any result.

In deciding upon the propriety of an operation, always regard it from your patient's point of view and in his interests, and on no account allow yourself to be influenced by any professional or personal bias.

In selecting the operation to be performed, choose the one that fulfils the most closely the objects you have in view—viz., the removal of the disease that demands removal with the least danger to life and the least sacrifice of parts. On no account let any personal preference for an operation, or personal success in it, induce you to deviate from this rule.

In fact, gentlemen, do to your patients what you would have done to you were you in their place, with your own knowledge and appreciation of the risks with which the proposed surgical act is surrounded; for your profession is a noble one. Be careful that no selfish ends be allowed to spoil the beauty of its objects. Let no professional prejudice or narrowness creep in to mar the thorough goodness of its results. Let your practice of surgery be based upon principles, and let your principles of surgery be based upon a higher one, and let that higher principle be no less a one than that which binds us all together as men—as Christian men; for, if we be surgeons, let us not forget that we are Christian men as well, and let our professional conduct be governed by the same influences that govern our conduct in daily life.

If the objects of the surgeon are high—and who is there that can deny it?—surely the principles upon which his acts are based should be high likewise. If the principles I have inculcated are high—and I admit they are,—let me remind you they are so only in order that they may help you onwards to fulfil manfully the noble objects for which you have entered at this hospital, and, as surgeons, to do something towards the relief of human suffering.

ON A FATAL CASE OF BLOOD-POISONING OF UNCERTAIN NATURE, PRESENTING SEVERAL UNUSUAL CHARACTERS.

BY DYCE DUCKWORTH, M.D., F.R.C.P.,
ASSISTANT-PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL; EXAMINER IN PRACTICE OF PHYSIC IN THE UNIVERSITY OF EDINBURGH.

THE case of which the following particulars are subjoined was one presenting several features of remarkable interest, and it therefore deserves publication. It seems, indeed, not an easy task, judging purely by its clinical characters, to place it in any clearly defined nosological category; but the nearest approach to such an attempt has been made in the title given above. Mr. Steele of Reigate, under whose immediate care the patient was, has kindly supplied to me the early history of the case.

X. Y., aged twenty-one, a slightly built, fair-haired gentleman, on the 26th September, 1875, began to complain of a noisy barking cough, and of some occasional spasmodic difficulty of swallowing. The day following he sought Mr. Steele's advice for these symptoms, and he further complained of some fulness about his neck. That gentleman at once detected an enlargement of the thyroid gland, and, finding no other physical signs, attributed the troubles described to that particular affection. Mr. Y. had never been robust, but had had no illness of any importance till four years previously, when he had a severe attack of typhoid fever. During the summer he had been somewhat overworked, and had not had sufficient holiday relaxation. The swelling was ordered to be painted with tincture of iodine, and a mixture was given containing three-grain doses of iodide of potassium in an ounce of infusion of gentian. Confinement indoors was also enjoined. It was noted that the action of the heart was somewhat feeble; pulse about 60; the skin was cool, and the appetite fairly good. The patient contrived to amuse himself in his room, and did not feel unwell. In the course of a few days the inspiration became gradually rather noisy, but was not difficult; and there was slight "brassy" cough, with the expectoration of a little grey mucus. The voice was also hoarse.

On the 10th of October I saw the case for the first time with Mr. Steele, and confirmed the above conditions. The thyroid body was then uniformly enlarged, symmetrical, hard, and firm. The finger could not be passed into the sternal notch. The lymphatic catena on the right side of the neck was enlarged, but not, or very slightly, upon the left side. There were no other enlarged lymphatic glands upon the body. The thyroid gland was only a little tender upon manipulation, and the integument over it was tense, cool, and non-adherent. The pulse was 60 per minute, regular, and the action of the heart was feeble. The tongue was a little furred, and a mawkish taste in the mornings was complained of. The bowels were comfortably relieved. The stomach was rather irritable, and there was a tendency to nausea. The chest was everywhere resonant on percussion, with the exception of some slight dulness under the manubrium of the sternum. The breath-sounds were modified generally by an apparently conducted tracheal note, but they were more shrill in the right suprascapular and infrascapular regions. The voice-sounds in these situations were also louder and more bronchial than on the left side.

Two small flattened tumours were found on the abdomen on the left anterior lumbar region, dusky-grey in hue, rounded and well-defined. They were tender when pinched up, and were distinctly in the integument. These had been observed for about ten days. The legs were natural in all respects. The spleen was not at all enlarged, and the liver was of normal dimensions. There had been a little soreness of throat and œdema of the uvula, and painting with equal parts of tincture of perchloride of iron and glycerine had been practised for relief of this. The urine was natural in quantity and appearance. The patient got up each day, and changed his room. No dysphagia, or very little, was complained of, but there was some irritability of stomach, and also occasional tendency to faintness and retching.

It was decided to increase the iodide of potassium to five grains for a dose, and to give as much of the carbonate of ammonia with it in infusion of gentian. The thyroid swelling was still painted with tincture of iodine.

On the 13th October there was no marked change, but some coryza had occurred, and the iodide was evidently ill-borne. About this time paroxysms of pain were complained of, issuing from the right side of the seventh cervical vertebra and shooting into the front of the right shoulder. At times these attacks were very severe. Opiates were given every four hours for the relief of this pain, and with some benefit. The nights were bad and the attacks of pain and retching were more frequent at night. The ointment of biniodide of mercury was now rubbed into the thyroid swelling. One application of this, however, caused vesication, and no more was employed. The breathing continued noisy, and at times there were short paroxysms of dyspnœa together with the attacks of pain and retching, requiring semi-erect posture in bed. The cervical glands continued to enlarge a little. During the two following days no decided change occurred. The pain still proved very annoying, and persisted in the same situation, and the faintness and retching continued. Usually a little bilious mucus was brought up. About the 15th October it was distinctly to be observed that the swelling of the thyroid gland was diminished and the whole organ was softer and less tense than before, perhaps even softer than a healthy gland, but the enlargement remained of symmetrical character, and there were still signs of tracheal and bronchial pressure as before. Some grey pearly masses of mucus were brought up after coughing, but the cough was not at all urgent. On the 17th October the pulse was 60, feeble; temperature normal; urine natural in appearance and void of albumen. The blood was examined microscopically, and the proportion of white cells was found to be normal, the red globules forming healthy rouleaux. The same dulness, and no more, was found at the manubrium on percussion, the resonance being good elsewhere over the chest. Air entered well into both lungs, but the respiration was markedly shrill and tubular, both in front and behind on the right side, less so on the left. The voice had a bleating character to bystanders, and on auscultation was bronchophonic over the upper half of right side. The thyroid body remained in about the same condition as when last noted—viz., uniformly enlarged, elastic, and symmetrical. The pain persisted in precisely the same situation. The patient directed attention on this day to some swellings upon his head, and on examination two firm node-like tumours were found upon the left parietal region, and two more upon the upper frontal region. These were situated in the pericranium, were only a little tender on pressure, but did not ache otherwise, and never at night. They had been noticed about a week previously by the patient himself, but he had not mentioned them.

Mr. Savory was invited to the consultation on the evening of this day, and he made a minute examination of the patient. It was decided to give quinine in three-grain doses every four hours, and to push the nourishment and wine more vigorously.

On the 18th October dorsal decubitus was no longer possible. The pulse was 72; respiration 14 in the minute, and noisy. The tongue was covered all over with a thick dirty-white fur. No material wasting was observable. The quinine was well borne. A bad night ensued. On the 19th, at 9.30 A.M., the pulse had risen to 90, was soft, but of fair volume. Respiration 20 in the minute. No fresh glandular enlargements to be felt. The spleen was natural as to size. Air entered both lungs well; breath-sounds very shrill. Tongue still more coated, and senses of smell and taste lost. The nares were dry, and inspiration through them impossible, though expiration could be managed. The attacks of pain became more frequent and severe, the sensation being compared to a feeling of dislocation. Some whiffs of chloroform were inhaled with slight relief to the paroxysms of dyspnœa. At 6 P.M. the pulse was 88; temperature 98·4° in axilla, 98·6° under the tongue. Two glands in the left groin had become enlarged and painful during the day, and the axillary glands were also somewhat enlarged. Strong beef-tea, eggs, and port wine were given as freely as possible. The quinine was increased to four grains and a half, with fifteen minims of tincture of perchloride of iron added to each dose. The pain now recurred at shorter intervals with increased severity, and was scarcely relieved by anodyne and hot fomentations. At midnight fifteen grains of chloral hydrate were given. Oct. 20th, at 1 A.M., a severe paroxysm of dyspnœa occurred, accompanied with retching. The respiration was very noisy (roaring) and rapid, like that of severe spasmodic asthma, and the distress increased. The shoulders were supported, fanning was employed, and some chloroform was given to inhale. Stimulants were also administered. No relief was afforded. The lips became more and more dusky, and the arms were thrown about wildly. Respiration ceased almost suddenly. Silvester's method of artificial respiration was practised for about fifteen minutes, and brandy was injected into the rectum. All efforts were in vain.

No post-mortem examination was obtained.

Remarks.—The illness just described lasted in all about four weeks. The family history afforded no clue whatever to the nature of it. The patient resided in a healthy country district, and had been, so far as was known, exposed to no insanitary or malarious influences. The earliest symptoms were, perhaps, referable to some irritation of the pulmonary branches of the vagi nerves. A condition of low health and feebleness had been reached for some time previously. The first coarse nutritional derangement to be recognised was a hard but uniform enlargement of the thyroid gland; and for some time most of the symptoms appeared to be due to this as a source of mechanical disturbance. Thus the altered respiratory sounds and voice and the peculiar cough seemed to be accounted for. This enlargement gradually progressed, and the cervical lymphatic system likewise became involved. These changes, however, could not be set down to any form of inflammatory growth, neither were there any indications of their being dependent upon tubercular, syphilitic, or cancerous cachexia; for the conditions present, and the history obtained, negatived all these hypotheses. Together with the involvement of the lymphatic glands, certain changes occurred in the integument over the abdominal wall and in the pericranium; and the physical signs in the chest afforded strong presumptive evidence of enlargement of the bronchial glands. At no period was there any splenic enlargement, and throughout the case there was absence of pyrexia. The blood also presented no signs of leukæmia.

Death by apnœa evidently ensued upon mechanical irritation of the pneumogastric nerves. The final paroxysm of dyspnœa, like those which preceded it, was accompanied by simultaneous retching and partial syncope.

In the absence of an autopsy, the primary cause underlying these processes has to be sought. To anticipate a view which might perhaps plausibly be held after a consideration of the facts of the case—viz., that the symptoms betokened the presence of a malignant tumour of the anterior mediastinum or of the thyroid body itself,—the fact may here be restated, that the latter organ became soft and yielding towards the termination of the case, and at no period presented any unevenness or evidence of involving other adjacent structures. Such conditions seem to be quite incompatible with the rapid spread of a malignant growth into or around the texture of this gland.[*]

No more reasonable explanation offered itself than that which was adopted—viz., that, owing to some peculiar form of blood-poison, the lymphatic system, in a large measure, including the thyroid gland as a part of it, became involved, and, by mechanical interference with certain nerves, gave rise to the varied symptoms which occurred, and which eventually caused death at a somewhat early period in the case. The integumentary and pericranial tumours may likewise be referred to the same cause.

It should be noted that the paroxysms of dyspnœa were not due to uncomplicated laryngeal spasm. There was never present pure stridor of laryngeal quality, and although it is not possible to aver that there was no such element in the dyspnœa, the characters of the respiratory trouble indicated the existence either of bronchial obstruction due to spasm, or, more probably, of spasm mixed with and dependent upon direct pressure from enlarged bronchial glands. Hence there never was any likelihood of affording even temporary relief by tracheotomy, for the obstruction was manifestly intrathoracic and beyond reach, and, further, the mechanical tension at one period exercised by the enlarged thyroid body had ceased to exist for some days before death. Had the thyroid gland continued to enlarge, and cause increased local pressure, an incision into the mesial line to relieve this might have been indicated. Direct compression by the gland upon the recurrent laryngeal nerves could hardly have proved more urgent towards the end of the case, but these branches may have been, and probably were, pressed upon by enlarged intrathoracic glands. The pain was, no doubt, of neuralgic nature, and due to pressure of glands upon a part of the brachial plexus.

Neither iodide of potassium nor quinine appeared to exert any beneficial influence upon the morbid process, and medical art was powerless to avert the bitter and untimely end of this remarkable and most distressing case.

Grafton-street, W.

CASE OF

ANEURISM OF THE ARCH OF THE AORTA;

OBSCURITY OF THE SYMPTOMS;
DEATH FROM RUPTURE INTO THE PERICARDIUM.

By HENRY BRIETZCKE, F.R.C.S.,
ASSISTANT-SURGEON TO MILLBANK PRISON.

The following case is so instructive, and resembles so closely a case reported in The Lancet of October 16th, by Dr. Frederick Robinson, that I venture to forward the notes for publication.

Corporal J. C——, aged thirty-one, a tall, muscular, well-built man, was received into the Military division of Millbank Prison on Sept. 22nd, 1875, under sentence of eighty-four days' imprisonment with hard labour, for deserting from the army in 1870. On admission he underwent the usual medical examination; he then stated that he was not feeling well, and was troubled with shortness of breath and a heavy cough. The following notes were taken:—

Present condition.—Unhealthy aspect; cicatrices of old abscesses on different parts of the body; badly nourished. Right lung: Posteriorly, puerile rough breathing; dulness on percussion and bronchophony in right interscapular region; absolute dulness on percussion in sternal half of subclavicular region and pectoriloquy at extreme apex; heart-sounds feeble and indistinct; laryngeal cough; no pulsation, thrill, bulging, or murmur over area of dulness; no abnormal sounds over vertebral column. Under these circumstances he was admitted into hospital.

History.—States that he first began to be ill in February, 1875, at New York; he got wet, and had a wheezing in his chest. In July he began to be very short of breath, and then consulted several doctors; he was told he had "bronchitis and asthma, with a tendency to consumption." His voice became hoarse in August while on his way to England. He has felt uneasiness in the left side of the chest for some time, but only when lying down; for the last four months he has been obliged to lie on his right side, as he felt "smothered" if he rested on the other.

Sept. 28th.—Ordered a mixture of dilute sulphuric acid with digitalis. Not so well. Temperature 101·2°; pulse 132. Has had a rigor, followed by febrile symptoms. Had a bad night; tongue furred. Vomited two or three times; this, he says, is caused by efforts to cough up phlegm which he feels in his throat. No expectoration to speak of. Breathing slightly quickened and of a laryngeal description; he cannot lie on his left side. On being questioned, he states that he has a slight difficulty in swallowing solids, that the bolus of food appears to lodge in the gullet somewhere towards the left side in front, and that he is obliged to take fluid to wash down every mouthful; this, he says, has lasted for two or three months. Notwithstanding this statement, he took a good dinner of meat and potatoes the day after admission, and was not unusually long over it. Never had hæmoptysis; no hereditary history of phthisis; no history of injury or strain.

30th.—9 P.M.: Pulse 120; respiration 33. Laryngeal breathing; and hard, paroxysmal, hoarse cough. The respiratory murmur is very deficient all over the left lung; in fact, very little air appears to enter, although there is no dulness on percussion or sign of consolidation. No pulsation in episternal notch; no bruit; no difference in the two radials; no pain in the back or chest. Ordered vapour of conium; and to have five minims of dilute hydrocyanic acid, twelve minims of spirit of chloroform, fifteen minims of ethereal tincture of lobelia, and one drachm of compound tincture of cardamoms, in water to an ounce and a half, every six hours.

Oct. 2nd.—9.45 A.M.: Pulse 120, full; tongue very foul; temperature 100·6°. Has had no sleep. Yesterday there was slight purulent expectoration. States that his breathing is relieved by the conium vapour. Excessive resonance on percussion over the left lung, deficient respiratory murmur, rhonchus; over the root of the lung, in the interscapular region, the breathing is extremely loud and bronchial, and the voice resounds through the stethoscope; but this is also to be found to some extent on the right side.

3rd.—11 A.M.: Face flushed and slightly dusky; orthopnœa on being raised up; pulse 140; temperature 102°.—1 P.M.: On carefully examining the chest, in consultation with Mr. Gover, the senior medical officer, we find absolute dulness on percussion in the right subclavicular region, with a sense of resistance to the finger, and this extends towards the sternum, especially over the second and third costal cartilages and corresponding intercostal space close to the sternum. In the right lung there is distinct vesicular murmur, and resonance on percussion; in the suprascapular region the breathing is loud and rough. During respiration the left chest scarcely rises at all; the right expands well. There is absence of respiratory murmur on the left side, and excessive resonance on percussion. Over the left interscapular region the breathing is loud and blowing. The lower intercostals on both sides fall in during respiration, and the diaphragm does not act well. No increased cardiac dulness; no pulsation or murmur. In the absence of indications of laryngeal disease, as well as of the symptoms characteristic of aneurism, we diagnosed a solid tumour, cancerous or glandular, compressing the left bronchus and irritating the left recurrent nerve.

4th.—10 A.M.: Pulse 128; bad night; cough troublesome; expectoration bronchitic and slightly purulent. Temperature 100·2°; face flushed, nostrils dilating; laryngeal breathing and cough.—5.15 P.M.: Severe attack of spasmodic breathing; duskiness of face and partial insensibility. These symptoms passed off on raising him in the bed, and his breathing became more natural.

---

[*] My colleague, Dr. Andrew, has reminded me of the opinion held by the late Dr. Southey Warter, of St. Bartholomew's Hospital, that cancerous growths often progress without exciting any pyrexia; and, so far, in this case this observation might have lent support to the view of malignant disease, but for other and weightier reasons this supposition could not be entertained. See also Wunderlich on Temperature.

5th.—10 A.M.: Reported to have had a second severe attack of orthopnœa in the night; is now slightly easier; pulse 125; temperature normal. Took his breakfast; has expectorated some pure pus unmixed with air-bubbles; lies on his right side; rapid emaciation since admission; pupils normal. On listening over the centre of manubrium a loud amphoric sound is audible, resembling air passing through a narrow tube; second sound of heart sharp and flapping. To have ethereal tincture of lobelia, 160 minims; iodide of potassium, eighty grains; camphor water to eight ounces: one ounce every four hours.—9 P.M.: Pulse 120; temperature 99°. At 2 A.M., while sitting up in bed, he suddenly called out "Jack!" to a fellow-prisoner, fell backwards, and expired.

Autopsy, eighteen hours after death. — Rigor mortis; body rather thin, but strong frame. On removing the sternum, a tumour was visible, projecting forwards slightly to the right of the median line, and occupying a position opposite the first, second, and third ribs; it was not adherent to the sternum, and there was no sign of erosion. Right lung adherent to the walls of the chest; left lung free. On opening the pericardium, a large quantity of clotted blood was found. The left vena innominata was pushed forwards in front of the tumour; the right occupied its normal position. The innominate artery arose from the upper and anterior part of the tumour, was pushed over to the left side, crossed the trachea obliquely, and immediately divided into carotid and subclavian. The left subclavian and carotid were somewhat pushed forwards and slightly elongated, but soon assumed their normal position. About half an inch below the part where the pericardium is reflected from the aorta and pulmonary artery, and to the right and somewhat behind the ascending part of the arch, was a small triangular opening, containing a clot of fibrine, where the tumour had given way. The ascending aorta and pulmonary artery were incorporated by a thickening of the visceral pericardium. The right division of the pulmonary artery passed behind the tumour, and was somewhat encroached upon. On opening the tumour, it was found to consist of a large sac, commencing at the termination of the ascending aorta, and involving the whole of the transverse part of the arch. The posterior wall was filled by a dense mass of laminated fibrine, firmly adherent and an inch thick. The ascending aorta contained no fibrine, but was dilated, and a pouch existed on the right side, immediately above the valve—apparently a dilatation of the corresponding sinus of Valsalva. The channel of the blood was in front, and the vessels arising from the transverse part of the arch were pervious, the deposit of fibrine being just posterior to their orifices. The thoracic aorta was thickened and atheromatous. The part where the tumour had given way contained no laminated deposit, being very thin, and directly in the current of the blood. With some difficulty the whole of the laminated fibrine was removed; and it was then discovered to be a true aneurism, all the coats of the vessel being intact. On removing the viscera of the chest, and dissecting from behind, the œsophagus was found to be flattened by the tumour, which was about the size of a small cocoanut. The left bronchus was much compressed; the right was free. There was also some pressure upon the bifurcation of the trachea. The left recurrent laryngeal nerve was involved in the tumour, or, rather, was compressed between it and the structures occupying the concavity of the aortic arch; it then passed up along the posterior surface. The trunk of the right pneumogastric passed down upon the posterior surface of the tumour. There were no signs of pressure upon the vertebræ.—Heart: Pulmonary valves healthy; right ventricle thin and rather dilated; left ventricle normal; aortic and mitral valves competent, the former a little rough. The muscular tissue was firm and normal under the microscope.—Lungs: The upper lobe of the left lung was bloodless, pale, and emphysematous; the lower lobe congested. Pus escaped from the cut bronchial tubes; slight roughness of the pleura at the base from old pleurisy. The right lung was crepitant and engorged. No emphysema, except at the anterior border of the middle lobe; no bronchitis. The liver, spleen, and kidneys were healthy.

For the following remarks I am indebted to Mr. Gover, the senior medical officer:—

In this case the symptoms and signs were those, not of an aneurism, but of an intrathoracic tumour, the result of nature's attempt at a cure. The case proves that a healthy condition of the heart is compatible with the near neighbourhood of a vast aneurism, and in this respect it tends to support the views of Hayden, Corrigan, and Stokes. The posterior direction of the aneurism explained the entire absence of thrill, pulsation, and murmur; but the absence of pain due to pressure on sentient nerves is not so easily accounted for. Dr. Hayden, in his learned and elaborate work on "Diseases of the Heart and of the Aorta," calls attention to the importance of a double sound over a limited portion of the vertebral column as in the highest degree suggestive of aneurism; but even this sign was absent, although the aneurism tended posteriorly. The obstruction of the left bronchus was nearly if not quite complete, and this forms an instructive and unusual feature in the case. Dr. Hayden considers that defective expansion of one side of the chest is not of much diagnostic value, and Dr. Stokes states that he has never met with an example of complete occlusion of a bronchus by the pressure of an aneurism. And yet it is certain that cases of aneurism occasionally occur in which the symptoms are, at first, limited to those produced by pressure upon the trachea or bronchi. In this instance the occasional laryngeal spasm and the absence of respiration on the left side allowed of an approximate diagnosis as to the seat of the disease, but its nature was left an open question. In estimating the difficulties of diagnosis, it must be remembered that only a few days before death this man had been received as being fit for imprisonment with hard labour. When examined, shortly after his arrival, the physical signs were those of compression of the trachea or bronchi, with high-pitched dulness over an area which was certainly suspicious. It was only towards the last that symptoms of laryngeal spasm were added to those of compression; and this, as pointed out by Dr. Hayden, is the usual order of events.

NOTES OF A CASE OF EMPYEMA.

By REGINALD G. ALEXANDER, B.A., M.B.,
PHYSICIAN TO THE BRADFORD INFIRMARY.

The following fatal case presents some interesting features in consequence of the destructive ulceration which took place soon after paracentesis thoracis had been performed, and which destroyed, in several parts of the chest, the intercostal muscles, the pleura costalis, and skin, leaving large holes through which three fingers could easily be passed and the thoracic viscera reached and touched. This state of things lasted for more than a month, with much less constitutional disturbance than might have been expected.

The patient, M. N——, came to consult me in March, 1872, after an illness of six weeks, during which he had complained of anorexia, cough, night-sweats, and loss of flesh. He spoke in a hoarse whisper, and had, in fact, all the symptoms of laryngeal phthisis; but under appropriate treatment (chiefly directed towards improving the general health) he recovered, gained many pounds in weight, declared himself quite well, and continued so until the 18th of December, when, after exposure to cold, he awoke in the night with acute pain in the left side, rigors, and dyspnœa so severe as to prevent him from calling his friends. Unfortunately he did not at first call in his medical attendant, and he only came under my notice on Jan. 11th, 1873, when he complained of pain in the left side and dyspnœa. The left side measured an inch and a half more than the right; the whole lung was dull upon percussion, and there was total absence of respiratory murmur throughout its whole extent. Temperature 101°; pulse 106. Linseed-meal poultices ordered, and a saline diaphoretic with compound tincture of camphor, from which great relief was obtained; but paracentesis thoracis could not be performed as the patient lived in an out of the way district.

Jan. 19th.—A sudden accession of pain with rigors came on (the symptoms pointing to the formation of pus within the cavity), and distinct fluctuation being felt at a spot two inches to the left of the left nipple and four inches below it, a trocar was introduced (the opening being made valvular), and three pints of pus were discharged, without causing the least faintness, dyspnœa, or other bad symptom. The temperature at the time of operation was 101°, pulse 120, and very feeble. A large quantity of pus was discharged into poultices, and objection was raised to washing out the pleural cavity. Iodide of potassium, quinine pills, and cod-liver oil were ordered. The appetite of the patient and his general condition improved considerably; the cough was slight, with mucous expectoration.

Feb. 2nd.—The patient declared himself better, and could lie on the right side; slight cough; appetite good; temperature 101·2°; pulse 130.

9th.—The discharge continued; patient weak, but appetite good; temperature 102°; pulse 130. The discharge became very offensive, and an ulcerative process commenced, which destroyed the pleura costalis, intercostal muscles, and skin, progressing from within outwards, and ultimately producing several large holes on the anterior surface of the left side of the chest, through which the finger could be easily passed.

March 3rd.—The ulceration advanced; the right leg became œdematous and an enormous size. Ordered warm sponging, a diuretic mixture, and the raised position for the leg.

16th.—The œdema of the leg disappeared entirely; temperature 101°; pulse 130, very feeble and sharp. Ordered wine, milk, eggs, all of which the patient took well.

30th.—Aphthæ in the mouth. Ordered the glycerine of borax, and an acid mixture of dilute nitro-hydrochloric acid with tincture of nux vomica three times a day.

April 3rd.—Aphthæ gone; temperature and pulse high; the holes in the chest-wall increased in size; three fingers could easily be passed into the thorax and the viscera touched. The pus had a gangrenous smell, but the breath was untainted.

7th.—Ulceration extended; *the ribs left bare*, and the cartilages exposed to view; *the lung plainly visible*. The patient ate and slept well, and declared that "but for the holes in his chest" he would soon be well. He began to spit pus. Temperature 102°; pulse 130.

10th.—The tissue-destruction increased; appetite good, but the patient began to despair of recovery.

11th.—Became suddenly worse; intense pain in both sides of the chest and abdomen; possibly perforation of the diaphragm. He died after twelve hours' great suffering. No post-mortem examination could be obtained.

Remarks.—The patient had always a bad aspect, but apparently a strong constitution, and it was a matter for regret that objection was raised to the introduction of a drainage-tube and the frequent washing of the pleural cavity with warm water containing Condy's fluid, &c., which might have prevented the gangrenous ulceration and caused the case to terminate favourably, as in two instances which have subsequently come under my notice. It is curious, however, to note how long a person can live in the sad condition to which this young man was reduced, and the practical deductions to be derived are—1. That there is little risk to the life of the patient, and small amount of discomfort experienced by him, in the operation of paracentesis thoracis, even when performed by a simple trocar and canula in place of the aspirator, and at a point of the chest by no means the seat of election. 2. That the danger of the free admission of air into the pleural cavity has been overrated in its *rapid evil effects* upon the vital powers.

Bradford.

EXCISION OF THE ELBOW-JOINT.

By WALTER RIVINGTON, M.S. Lond., F.R.C.S. Eng.,
SURGEON TO THE LONDON HOSPITAL.

The excellent results obtained by Mr. Maunder by the method of operating which he recommends are no doubt correctly attributed by him to preservation of the natural relations of the triceps to the fascia of the forearm and anconeus muscle. The first surgeon who pointed out the advisability of avoiding transverse incisions across the triceps and the fascia appears to have been Dr. R. Hodges, of America, as stated by Mr. Bryant in his work on the Practice of Surgery, and this was some years previously to the inculcation of the same doctrine by my colleague Mr. Maunder. In mentioning this fact I have not the least desire to detract in any way from the credit justly due to Mr. Maunder, for it is probable that but for the greater prominence which he has given to the improvement it might have been confined to a small circle of operators. I think, however, that Dr. Hodges's claim should not pass without some recognition. Other surgeons, too, who have been in the habit of adopting the method of excision of the elbow by a single straight incision through the triceps and fascia down to the bone, have, consciously or unconsciously, retained the relations of the triceps and the fascia, together with the anconeus. In point of fact, the relations could not well be disturbed. It is only where a H- or ⊣-shaped incision is adopted that this can happen. Even with these methods very good results may be obtained in some cases.

In January, 1872, I operated on a smith, fifty-four years of age, for rheumatoid disease of the left elbow-joint, attended with great infiltration of the tissues of the arm and forearm. The parts were so brawny, thick, and inelastic, at the time of operation, that I was obliged to make a transverse incision through the fascia and triceps on the outside in order to obtain access to the bones. The ultimate result was all that could be desired. The patient could have knocked anyone down by the action of the triceps alone. He was unfortunately nearly blind, and could not follow his occupation. For three years he remained perfectly well. In the spring of the present year he injured the arm, and an attack of inflammation ensued, with formation of an abscess over the new joint. A small sinus at present exists, and the arm is weakened, but the power of extension remains.

In another case, occurring in 1871, in which I had operated by the straight incision, without knowing the particulars of Mr. Maunder's method, the persistence of a sinus after operation led me ultimately to divide the ligamentous union of the bones, with the triceps and fascia, transversely. The sinus closed by granulation, the bones, triceps, and fascia reunited, and the lad had a perfect arm. The case was one of synovial disease of long standing, and the triceps was atrophied before operation. Not many months ago I met the boy in the street, where he demonstrated flexion, extension, pronation, and supination to me, and stated that the limb was in every way as good as its fellow.

I mention these cases (which were shown to the Hunterian Society) to prove that, although it may be better to adopt the straight incision with the precautions insisted on by Mr. Maunder, yet equally good results are obtainable even when the triceps and fascia have been subjected to an additional transverse incision. In only one case have I employed the H-shaped incision. The triceps was atrophied, there were several sinuses, and the patient was so unhealthy that I advised amputation; but as the friends would not consent to the removal of the limb, I practised excision. The ultimate result I do not know, as the patient was sent to the seaside, and I have not seen her since. Under any circumstances, the wasted state of the triceps, which was of a pale yellow colour, would have probably precluded the restoration of extending power. Mr. Maunder was fortunate in meeting with a patient suffering from accident, and not from disease, and therefore with a triceps in a perfect state of efficiency. He was also fortunate in meeting with a patient capable of winning a billiard match. Had either of my patients been similarly gifted, he would have been equal to the occasion. Nevertheless, I fully admit the value of Mr. Maunder's demonstration of the *rationale* of the straight incision, and believe that the straight incision should be practised wherever it is possible to do so.

Finsbury-square.

West Kent Medico-Chirurgical Society.—The second meeting of the session was held at the Royal Kent Dispensary, Greenwich-road, on Friday, November 5th, Dr. J. N. Miller, president, in the chair. Dr. J. Braxton Hicks brought forward some cases illustrating the effects of large doses of quinine in some cases of puerperal fever. The next meeting will be held on Friday, December 3rd, at 8 p.m. precisely, when Dr. Tilbury Fox will read a paper.

ST. BARTHOLOMEW'S HOSPITAL.

COMPOUND DEPRESSED FRACTURE OF SKULL; PARALYSIS OF RIGHT ARM ON SIXTH DAY AFTER RECEIPT OF INJURY; ELEVATION OF DEPRESSED PORTION OF BONE; RECOVERY WITH USEFUL ARM.

(Under the care of Mr. THOMAS SMITH.)

THE following case, for the notes of which we are indebted to Mr. Edward Milner, surgical registrar, illustrates some of the difficulties that occasionally present themselves during the treatment of depressed fracture of the skull in children without primary compression. The majority of the best authorities agree that in any case of depressed fracture of the skull, but especially when it occurs in children, the proper course to pursue is not to interfere with the depressed portion of bone if there be no symptoms of compression. It will be observed that in the subjoined case the symptoms of compression did not show themselves until the sixth day after the accident. Sudden paralysis of motion and sensation then appeared, and other symptoms of brain-pressure gradually supervened. The line of practice to be adopted was clear. Accordingly, Mr. Smith elevated the depressed bone and let out a quantity of pus and disorganised brain-matter. After this the patient progressed satisfactorily. There is, however, another point of interest in this case—namely, the great and persistent lowering of the temperature in the paralysed limb. As a rule, in such cases the temperature is not more than one or two degrees below normal, and tends to rise to the healthy standard in a few days. In this case the paralysed limb remained about 6° F. below the normal for many weeks.

Edward N——, aged six, a previously healthy boy, was struck on the left side of the head by a heavy piece of wood which had fallen from a third-storey window. On admission on the evening of June 8th, immediately after the accident, he was found to have sustained a contused and lacerated wound of the scalp, about an inch and a half in length, and situated about the level of, but slightly anterior to, the left parietal eminence. At the bottom of the wound a depressed portion of bone could be distinctly felt, the point of a probe being stopped against a distinct ridge when passed over the line of fracture. There was no paralysis of any part of the body. Patient was very sick and somewhat heavy, but quite conscious, and understood everything said to him. There was no bleeding from the nose, mouth, or ear, and only very slight bleeding from the wound. Pupils equal, slightly dilated, and acting readily to light; breathing noiseless, regular, and natural.

June 9th.—Is quite conscious, and understands what is said to him. Has been sick since admission. Is not noisy, but very restless and irritable, and constantly calling out. Had no sleep last night. Pupils equal and acting to light; temperature 98·2°; pulse 78, irregular in force and frequency; respiration 22, natural.

10th.—Restless and irritable, throwing himself about in bed, and constantly crying out. Still very sick; indeed can keep nothing whatever upon his stomach. Slept badly. Bowels not open since the accident. Pulse 96, good volume, more regular; temperature 98·3°; respiration 20. Wound looks well; very free discharge of somewhat offensive pus. To take ten grains of chloral hydrate in an enema.

11th.—Bowels open very freely this morning; still sick, but not so sick as in the previous twenty-four hours; still very irritable and restless, calling out constantly when awake, and throwing off the clothes; pupils equal, acting readily to light, slightly dilated; has kept nothing upon his stomach in the way of food since admission. Respiration 28; temperature 98·4°; pulse 112, regular, but feeble and compressible. To be fed every four hours by an enema composed of two eggs and a pint of beef-tea.

12th.—Very much better; much less irritable; no more sickness. Temperature 99°; respiration 24; pulse 108, much better volume and quite regular. Slept well; bowels open; very free discharge from the wound.

13th.—Much better; slept well after ten grains of chloral hydrate; no more sickness; takes food well by the mouth.

14th.—Slept well; much more quiet, and apparently very much better until 9.30 A.M., when complete paralysis of motion and sensation of right arm suddenly occurred. Up to 9.30 A.M. both motion and sensation had been perfect, for he was seen holding a piece of bread, and also moving a cup of milk with his right hand within a few minutes of that time. The paralysis supervened without the least apparent constitutional effect upon the patient. He was under the observation of the registrar when it occurred, who noticed him using his arm freely, and within five minutes called the attention of the nurse, who was washing the patient at the time, to the fact that the arm was hanging helplessly by the side. Within an hour of the coming-on of the paralysis patient became very much more irritable and restless, calling out constantly, complaining of his head, and hardly keeping the clothes on him for a moment. Face had also become slightly drawn to the right side.

A consultation having been held, Mr. Smith had the patient removed to the operating theatre and placed under the influence of chloroform. He then enlarged the wound with a sharp pair of bone forceps, cut off sufficient bone to make room for the point of an elevator beneath the edge of a depressed portion of bone about two inches long in the greatest diameter. This depressed portion he then, by means of the elevator, brought up to the level of the surrounding skull, letting out at the same time about a drachm and a half of pus and dirty brain-matter. A poultice was ordered to be applied to the wound, and the patient sent to bed.

15th.—No change in condition of arm. Face straight and expression vacant. Has lost all power of articulating words; makes a noise, but cannot form words. Has had no sleep; very restless, constantly calling out and getting out of bed. Is very feeble. Bowels open five times in twelve hours since operation, the motions containing a little blood. Pupils equal, dilated, acting. Temperature 101·1°; pulse 140, very feeble but regular; respiration 36.

16th.—Aspect much improved. Arm still in same state as regards motion, but it gives him some slight pain when pinched. Pupils as yesterday. Bowels open four times in twenty-four hours; motions very loose, but containing no blood. Slept well, and is not nearly so irritable or restless. Pulse 116, regular, but very feeble; temperature 98·3°; respiration 28.

18th.—Aspect and power of articulation much improved, but within the last twenty-four hours the left side of the face has become drawn to the left side, and tongue protruding slightly to the right side. Patient is much less restless. Slept well. Appetite much improved. Bowels open three times in twenty-four hours; motions still very loose.

19th.—Power of articulation much improved. What he says now can be understood fairly well. No improvement in condition of arm. Pupils equal. Bowels opened four times in last twenty-four hours, and still very relaxed. Temperature 98·4°; pulse 114.

21st.—General aspect very much improved. Sensation in arm much better, and he is able to raise the limb for the first time; he cannot move or close the fingers. Bowels open; less relaxed. Temperature 97·5°.

23rd.—Gaining power rapidly in arm; is able to close the fingers so as almost to grasp an index finger. Face remains drawn to the left side as before. Poultice constantly applied to wound, from which there was free discharge. Bowels open once; not much relaxed. Temperature 98·4°; pulse 110.

25th.—Not nearly so well; has been very sick; speech not so clear; less power of movement in the arm; complains of much pain in the head. Bowels opened yesterday, but not to-day. Free discharge from the wound. Pulse 96, very feeble and slow; temperature 97·5°.

28th.—Still very sick; appetite bad; bowels open; expression very vacant. Temperature 98·4°; pulse 114, very feeble, but regular; arm not improved.

29th.—Bowels open very slightly after two enemata of oil. Cheek still drawn to the left; saliva occasionally running from mouth; tongue protruded slightly to the right. Still very sick. To have four grains of calomel on tip of tongue.

30th.—Bowels open very freely. Sick only once since. General aspect very much improved. Appetite better. Arm about the same. Wound looks well; very free discharge; poulticed constantly, and syringed with Condy's fluid and water.

July 1st.—No more sickness; bowels open freely; more power in arm; slept well; takes his food well. Temperature 98·2°; pulse 90, of very much better volume, and regular.

2nd.—Passed a good night. Temperature 98·4°; pulse 94. The arm is gaining power, but is still much colder than the other; sensation is perfect. Wound looks well; discharging freely; treated as before. Bone can no longer be seen at the bottom, being completely covered in.

7th.—Since last note has been gaining power slowly in the arm, but it is becoming more rigid; the flexors are gaining over the extensors of the forearm, and the hand is constantly closed, the fingers being extended by patient only with the greatest difficulty. The right arm is 6° Fahr. colder than the left. The left pupil was noticed to be slightly more dilated than the right for the first time to-day; both act readily to light; face is still drawn to the left as before. Temperature 98·2°; pulse 104, quite regular and of good volume.

14th.—Less rigidity and more power in the right arm; fingers easily extended; noticed to be slightly deaf in the left ear; arms have the same relative temperature as before; very little discharge from wound. Water-dressing applied. Temperature 98·4°. Sleeps and eats well.

20th.—Wound all but healed; patient allowed up; deafness on left side slightly increased; face still drawn to the left side as before; tongue protruded straight. Slowly gaining power in the right arm.

27th.—Wound completely healed. Allowed in the hospital square daily. Has no pain in his head; sleeps and eats well; arm is gaining strength; fingers readily extended. Right arm wasted, being much smaller than the left, and there is still a difference of 6° F. in temperature against the right arm. Speech quite clear; deafness about the same; and the face is still drawn to the left side.

Aug. 12th.—Patient discharged to-day, with the wound in the head completely and soundly healed. Face still drawn to the left side; tongue protruded straight. Left pupil slightly more dilated than the right; both pupils acting freely and readily to the light. Still deaf in left ear, and this deafness is slightly increasing. The left arm is larger than the right, and is warmer by 5·6°F. There is very good use and movement in the right arm and hand, he is able to button his coat with it, and the strength in it is still improving. Speech has perfectly returned, and he swears with great volubility. He seems rather stupid for his age, and his mother does not think him so bright as before the accident. He has had during the last fortnight three most violent, almost maniacal, outbursts of temper.

CHRISTCHURCH (CANTERBURY, NEW ZEALAND) HOSPITAL.

STRICTURE OF THE URETHRA; DILATATION; CURE.

(Under the care of Mr. Courtney Nedwill.)

In the "Mirror" of Jan. 23rd there is a series of seven cases of stricture of the urethra treated by Mr. C. Nedwill on the immediate dilatation plan. Subjoined is another series of six cases.

Nos. 6 and 7 of the former series have presented themselves for examination since the report. In February a No. 12 bougie was easily passed in No. 6 case, and in July last, without the slightest resistance, the same sized instrument was introduced in No. 7 case, an interval of six months having elapsed since the previous trial.

Case 8.—R. P——, aged twenty-eight, labourer, was admitted into the hospital on Oct. 17th, 1874, with stricture of the urethra, about the beginning of the membranous portion, from which he has been suffering for seven or eight years. Four years ago, he says, an abscess formed in the perineum, leaving a fistula through which urine escaped for two months. A No. 4 bougie only could be introduced through the stricture on his admission, but by the 23rd Sir H. Thompson's dilator was used. On the 29th a No. 12 bougie passed freely, and again on Nov. 24th, and the patient was completely relieved from all his symptoms.

Case 9.—J. F——, aged thirty-nine, a cook, was admitted into the hospital on Oct. 27th in a very weak, emaciated condition. Had tried to commit suicide before admission on account of suffering much pain, and having great difficulty in passing water. The urine was loaded with albumen. A stricture of the urethra was detected at the bulb, through which only a No. 3 bougie could be passed into the bladder. Mr. Nedwill gradually dilated every second or third day until a No. 8 was used, but the difficulty in introducing this sized instrument was so great that nothing more was done just then, as there was so much albumen still in the urine. The patient was kept in the hospital till about the 1st of January, 1875, when, finding the albumen had very considerably diminished in quantity, and the stricture had contracted, Mr. Nedwill determined to use Sir H. Thompson's dilator. The patient never had a bad symptom afterwards, and was discharged cured on Jan. 26th, a No. 12 bougie passing easily into the bladder.

Case 10.—G. S——, farmer, aged forty, admitted on Dec. 5th, 1874, with stricture of fifteen years' standing, about two inches from the orifice of the urethra. A No. 3 bougie only could be passed on admission, but in a few days Richardson's dilator was used. A No. 12 catheter was left in the bladder, and the man had never a bad symptom afterwards. At the end of March last a No. 12 was passed with ease, and again about Aug. 26th, 1875.

Case 11.—W. G——, aged twenty-three, applied for relief of retention of urine on the 15th January, 1875. For two years past he had had great difficulty in urinating, and his health was becoming seriously affected. A warm bath and the sedative solution of opium were ordered, and afterwards, notwithstanding the most patient attempts, no instrument could be got through the stricture beyond the bulb. During the night the patient had repeated doses of opium and several baths, but failing on the following day to reach the bladder, Mr. Nedwill sent the patient into hospital with the object of aspirating the bladder, which he did, and drew off two quarts of offensive urine. Next evening fresh attempts were made to pass a bougie, but in vain, so that the aspirator was used again. After using several No. 1 catgut bougies, Mr. Nedwill cut the end off a very small No. 1, and passed right down to the point of it a fine wire. With this bougie he managed, after nearly half an hour's steady pressure, to get it engaged so much in the stricture as to give to the hand the sensation of its being stuck in wax. It was left in for fifteen minutes, and then, after steady continuous pressure, kept up for about twenty minutes, Mr. Nedwill had the satisfaction of feeling it pass into the bladder. Without this wire it is certain no bougie ever yet made could have been passed; the wire gave it just enough rigidity to allow of a continued pressure being kept up. This bougie was tied in the bladder for twelve hours, and on its withdrawal a No. 3 went in easily. In a few days Sir H. Thompson's dilator was used. From this date until August 26th, 1875, a No. 12 bougie had been passed on several occasions without difficulty. It should be mentioned, that for several weeks after the operation this man was in a very critical condition. He passed during this time large quantities of blood and pus, and although the stricture is now apparently quite cured, the patient still suffers from an irritable bladder.

Case 12.—R. T——, a sailor, aged thirty-two, admitted on April 28th, 1875, with stricture of urethra. Has had difficulty in passing water for nine years, with occasional attacks of complete retention. A caustic bougie, which was said to have been followed by temporary relief, had been used some time before. He soon relapsed, however, and on admission, as no instrument could be passed, and as the bladder was very considerably distended, the bladder was aspirated above the pubes, and three pints of urine drawn off. The next day he passed urine in a very small stream, almost guttatim. For three weeks Mr. Nedwill was unable, in spite of repeated attempts, to get an instrument through the stricture, which was about the junction of the bulbous and membranous portions; and during this time he had a hot bath night and morning, which enabled him to pass his urine with somewhat less difficulty. At length a No. 1 elastic bougie was introduced into the bladder, and on its withdrawal after twenty-four hours a No. 3 was passed with ease. A severe shivering fit, however, coming on, no more instruments were passed for a week. On several occasions afterwards Mr. Nedwill failed in getting through the stricture, and rigors followed these attempts so frequently that the patient was put under chloroform, and Sir H. Thompson's dilator was forced through the stricture, the finger being kept in the rectum to guide the instrument. A No. 12 silver catheter was passed, but had to be taken out a few hours afterwards on account of rigor. Next day the patient looked very ill, temperature 104°, and complained of a feeling as if he "had been hammered all over." Quinine in ten-grain doses was administered night and morning, and the man made a good recovery. Discharged July 10th. Since discharge a No. 12 catheter has been passed.

Case 13.—W. J——, aged thirty-three, a sailor, admitted on June 11th, 1875, with hæmaturia and history of stricture. A No. 4 bougie was held firmly in front of the bulbous portion of the urethra. After a fortnight's residence in the hospital, as there was no albumen in the urine, a No. 4 bougie was used with difficulty. This, however, was followed by rigor and constitutional disturbance. Quinine having been given for some days, Sir H. Thompson's dilator was passed through the stricture; but on its withdrawal a No. 10 catheter only could be introduced. Rigor, very high temperature, and a sharp attack of orchitis followed. Quinine was administered freely, commencing with a ten-grain dose, followed by two grains and a half every four hours. A few days before the patient's discharge—convalescent on the 5th of August—a No. 12 bougie was passed easily. Again a severe rigor followed, but no further ill effects.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

At the ordinary meeting of this Society, held on the 16th inst., the President, Mr. G. Pollock, in the chair, a very large number of specimens (many of them of great interest) were shown. Among them we may specially indicate a remarkable case of Embolism of the Pulmonary Artery, shown by Dr. Fagge; a specimen of Tubercular Lupus of the Tongue and Palate, by Mr. Fairlie Clarke; and two interesting examples of Congenital Malformation of the Œsophagus, due to the arrest in development of the anterior part of the alimentary canal, the pharyngeal portion not becoming blended with the lower end of the tube; the case formed thus a parallel to the more frequently occurring condition of atresia ani.

Mr. Marcus Beck and Dr. Coupland were nominated auditors.

The following gentlemen were elected members of the Society: — W. M. Ord, M.D., H. Royes Bell, F.R.C.S., H. Hugh Clutton, F. R. Cross, J. P. Irvine, M.D., J. B. Jessett, F.R.C.S., E. E. Noel, M.D., and H. A. Lediard, M.D.

Mr. Maunder exhibited a specimen of Cancer of the Male Breast, which had been removed from a patient forty-two years of age. It commenced with soreness and ulceration of the left nipple, and on removal the tumour, which appeared to be scirrhus (but it had not been examined microscopically), was of the size of a Tangerine orange. The patient also was present, and, although eighteen months had elapsed, it could be seen there was no recurrence in the scar. An enlarged gland in the axilla existed at the time of operation. The specimen was referred to the Morbid Growth Committee.

Dr. Goodhart showed a recent specimen of Insular Sclerosis of the Brain and Spinal Cord, taken from a female patient who had for some time past shown the characteristic symptoms of the disease—viz., spasmodic movements of the limbs and head, increased by effort, nystagmus, staccato speech, without impairment of sensibility, electromotility, &c. Two days before death, which took place from pneumonia, there was paralysis of the palate. The white matter of the brain and cord presented numerous patches of sclerosis.

Dr. Coupland brought forward a recent specimen of Ulcerative Endocarditis, which presented a good example of so-called aneurism of the mitral valve. The left side of the heart was dilated and hypertrophied, and projecting upwards into the auricle was a pouch, the size of a bean, formed by a protrusion of the auricular surface of the anterior mitral cusp. The ventricular surface of the cusp showed an ulcerated hole near to the attached border of the valve, large enough to admit the tip of the little finger, leading into the aneurism, which was filled with fibrine. The remainder of the valve was quite natural, but the aortic valves were thickly covered by vegetations, the central cusp being widely perforated. There were two infarctions of old date in the spleen, one of great size. The specimen was obtained from a male patient, forty years of age, who had been six days in hospital. The symptoms, which were chiefly those of præcordial pain and cardiac dyspnœa, were of five weeks' duration. There was no history of rheumatism. Dr. Coupland remarked upon the formation of aneurism of the mitral valve from ulceration on the ventricular surface, and inquired whether in most cases this was not secondary to the disease of aortic valves.—Dr. Hilton Fagge pointed out the effects of friction on the endocardium as productive of local endocarditis, a fact first observed by Dr. Hodgkin, and insisted on by Dr. Moxon, who some years ago showed specimens in favour of this view. Did the vegetations on the aortic valve in the present case come in contract with the mitral at the seat of ulceration?—Dr. Coupland said that it was just this question of friction from the aortic vegetations on the mitral valve that he wished to raise when he asked whether the lesion on the latter could be considered secondary to the aortic disease. That such was the *modus operandi* in the present case was very likely, seeing that there were two erosions on the mitral valve, above the large ulceration, which would have come in contact with the aortic vegetations. But these vegetations were not long enough to reach the site of the aneurism, although the existence of the splenic infarction was presumptive evidence in favour of their having done so at an earlier period.

Dr. Crisp exhibited a specimen of United Fracture of the Humerus from a Gorilla, remarking that it was of interest as showing how completely union had taken place. He also showed several specimens of Rickets in Pheasants which had been reared under hens, and thus under artificial conditions. The long bones were greatly distorted and wanting in ossific material, their ends being enlarged. The skull and spine were not much affected.

Dr. Fagge showed an interesting specimen of Embolism of the Pulmonary Artery obtained from a patient who had died of enteric fever under the care of Dr. Mumford. Death occurred in the fourth week of the disease, with symptoms of dyspnœa, following an attempt to get out of bed. The ulcers in the intestines were in process of cicatrisation, some presenting adherent sloughs. The lungs were engorged. The valves of the heart were healthy, and the organ contained gelatinous decolourised clot. The base of the pulmonary artery was filled by loose black coagulum, but lying across the vessel at its bifurcation was a clot which at first seemed as if it were made up of four distinct cords twisted on one another. It was really a long cylindrical clot folded upon itself; it bore no marks of the valves upon its surface. The cava, iliac, and femoral veins were empty. Dr. Fagge supposed that the long clot in question came from one of the femoral veins, had become detached and washed off into the pulmonary artery, and then folded up across the main division of the vessel. There had been no signs of thrombosis in the leg, so that it was probable the detachment had occurred close upon the formation of the clot.—Dr. Crisp thought the view held by Dr. Fagge should be received with caution.

Dr. Fagge showed two specimens of curious Pouches from the Ileum, which he proposed to call "distension diverticula." The first was obtained from the body of a emale who died with symptoms of acute strangulation. Gastrotomy had been performed, and a small knuckle of ntestine was found lodged in the right femoral ring. At one part of the intestine there was a pouch projecting between the folds of the mesentery. The second case presented two or three similar diverticula, but there was no history of obstruction in this case. Dr. Fagge suggested that these diverticula were produced by distension of the bowels, leading to a protrusion of the mucous membrane, and that their presence indicated previous intestinal obstruction. The diverticula showed no tendency to return after the intestines were opened.

Dr. BARLOW exhibited a specimen of Tubercle of the Pancreas. He remarked on the existence of this affection being either denied or ignored by most writers on morbid anatomy. It is, however, mentioned by Foerster and Friedrich, but chiefly in the form of cheesy nodules or cavities, and its existence in acute miliary tuberculosis has been denied by Klebs. The specimen shown confuted this latter view, since it was an instance (a child aged one year and eleven months) in which pale white granulations, the size of a pin's head, occurred in the pancreas in a case of general tuberculosis, granulations occurring in the lungs, kidneys, ureter, bladder, and peritoneum. Microscopically the structure of the nodules was that of tubercle, becoming caseous in the centre.

Mr. MARSH showed a specimen of Osteo-Sarcoma of the Superior Maxilla which he had removed from a boy fourteen years of age. The disease had been in progress for six months, and when seen there was a swelling on the face just above the bicuspid teeth; it did not involve the hard palate. Exploratory puncture showing it to be a new growth in the antrum, Mr. Marsh removed the whole of the superior maxilla, which was done with facility, it not being found necessary to prolong the incision along the orbit. Mr. Butlin had examined the tumour, and pronounced it to be an osteo-sarcoma. Mr. Marsh referred to another case of sarcoma of the antrum in a child which he had removed by scooping a short time ago. There had been no return.

Mr. FAIRLIE CLARKE showed a specimen of Tubercular Lupus of the Tongue, Soft Palate, and Gums. The patient was a bricklayer eighteen years of age, who had been under the care of Mr. Teevan at the West London Hospital. There was no family history of phthisis or syphilis. The whole of the buccal mucous membrane was thick, velvety, and infiltrated; there was a large ulcer on the left side of the tongue, and the whole of the soft palate had ulcerated away. The salivary glands were considerably enlarged, but there was no implication of the lymphatics. Dr. Sparks and Mr. Butlin reported that there was an infiltration of small round cells in the submucous tissues. It was singular in there being no ulceration of the skin, lupus affecting a mucous membrane primarily being very rare. A few cases of tubercular ulceration had been put on record, chiefly by continental writers.—To a question put by the PRESIDENT as to whether the soft palate had cicatrised, Mr. Clarke replied in the negative.—Dr. FAGGE alluded to one case of tubercular ulceration of the tongue which he had examined. The floor of the ulcer was covered by yellowish grains, as in "tubercular" ulcers of intestines. He recalled another case, in which tubercular ulceration of the larynx had invaded the soft palate.—Mr. MARSH said that several years ago tubercular ulceration of the tongue had been described by Sir James Paget.—Dr. GOODHART inquired whether the patient died of phthisis?—Mr. SPENCER WATSON, acknowledging the rarity of primary lupus on mucous membranes, said that he had met with it on the nose; it was then a form of erythematous lupus.—Mr. CLARKE, in reply, said that the patient did not die from phthisis, but from the local mischief.

Mr. MAUNDER showed a Fatty Tumour from the Axilla of a Male, which before removal simulated a greatly enlarged mamma.

Dr. GOODHART showed a specimen of Hydatid Disease of the Heart from a male subject who, up to the time of his death, which occurred suddenly, had been apparently in perfect health. The pericardium was much thickened; its chamber contained from three to four ounces of pus, which had apparently proceeded from an old hydatid cyst lodged in the septum ventriculorum. The cyst bulged into the ventricle. Numerous hooklets and much membrane occurred in the cyst, the suppuration of which had caused the patient's death.

Dr. DOWSE showed a specimen of Syphilitic Growth in the Posterior Cerebral Sinuses. The patient, a male, thirty-nine years of age, suffered from headache, diplopia, vomiting, earache, and otorrhœa. There was neuro-retinitis, but no paralytic symptoms. Over the right frontal eminence there was a depressed cicatrix, from which necrosed bone had come away. The outer surface of the cranium was much nodulated; the dura mater was adherent posteriorly to the brain, and the sinuses terminating in the torcular Herophili were all found to be occupied by a growth having the character of granulation tissue. The disease was more advanced in the right than in the left side.

Dr. DOWSE also showed a specimen of Glio-Sarcoma of the Brain, from a case in which the symptoms commenced two years before death with right-sided convulsions. The patient had a peculiar gait, as if he wanted confidence; it was not ataxic, nor that described as characteristic of cerebellar disease, and it was shown rather in slow than in rapid progression. Intellect was clear; sight good. The optic discs were hazy. There was complete absence of paralysis. Death was preceded by a series of epileptiform fits. At the autopsy a soft pink-coloured mass was found on a level with the corpus callosum replacing the anterior part of this structure. The growth was cone-shaped, the base being directed forwards upon reaching the pineal gland, and it adhered slightly to the corpora striata. It was composed of round, oval, and spindle cells imbedded in fibrous stroma, and in parts presented calcification. It arose probably from the choroid plexus.

Dr. GOWERS exhibited a specimen of Glioma of the Brain. The tumour, which showed well the infiltrating character of such growths, was situated beneath the left superior parietal lobule, the convolutions being continued over it. It appeared on the surface at the lower part of the lobule, and was seated mainly in the middle of the radiating fibres of the corpus callosum, reaching to the roof of the lateral ventricle. Microscopically it was made up of minute fusiform and angular cells, with fine filaments constituting the matrix. The patient had been the subject of complete right hemiplegia for two months before death, and of *slight* right hemiplegia for two months before that. Each attack of paralysis came on suddenly. During the last six weeks of his life he had several convulsive seizures, the movements preponderating on the left side, which in the last few days of life became paralysed too. There was double optic neuritis. The hemiplegia was probably due to the involvement of the fibres of the corpus callosum, which would explain further the extension of the paralysis to the left side. Dr. Gowers pointed out that the sudden onset of the hemiplegia was interesting, together with the absence of any convulsions in the early progress of the disease. The patient had some loss of memory for words, but no actual aphasia.

Mr. MARSH showed for Dr. Ilott two specimens of Malformation of the Œsophagus. In each case the pharyngeal end of the gullet formed a cul de sac, a little below the cricoid, while the remaining portion of the tube ended in the trachea at its bifurcation. One of the specimens was from a child born at the eighth month, which survived four days; the other, born at full time, died in a week, some of the food getting into the air-passages. The malformation was obviously due to arrest of development. Mr. Holmes had questioned whether in such cases operative measures could be taken to restore the continuity of the tube, but the great depth of the structures would render it very difficult.—Dr. ILOTT, in reply to Mr. SMITH, said that the children were born of different mothers. One of them also presented a malformation of the vessels of the neck, the right subclavian artery being given off last from the arch of the aorta, and passing behind the trachea; and the two carotids coming off from a common trunk.—The PRESIDENT said there was a preparation in St. George's Hospital museum of a pouch-like expansion of the œsophagus, with no constriction below it. It had existed for years, and its presence was recognised during life.—Mr. DORAN also alluded to a specimen at the Royal College of Surgeons, which had occurred in a high dignitary. It had given rise to much dysphagia.—Mr. WAGSTAFFE referred to a similar case related in a recent number of the *Journal of Anatomy*.—Mr. ILOTT said his cases were purely congenital malformations, the pharynx ending blindly, but the mouth being in direct communication with the trachea and lower part of the œsophagus.

Mr. CLEMENT LUCAS showed the Air-passages after Tracheotomy, obtained from a child who had swallowed some boiling water. He had brought the specimen as it illustrated a method of operating which might sometimes be had recourse to—viz., direct incision through soft parts and trachea at the same time. No chloroform was administered. There was but little bleeding, and no difficulty in introducing the tube.—In reply to Dr. MURCHISON, Mr. LUCAS said there was no membranous exudation on the larynx, but much puckering of the glottis; and in answer to Mr. T. SMITH he said it was the first time he had so operated.

The Society then adjourned.

CLINICAL SOCIETY OF LONDON.

THE ordinary meeting of this Society took place on Friday, Nov. 12th, Mr. Callender, Vice-President, in the chair. There was a large attendance of members of the Society, and much interest was taken in the debate, which was generally supposed to be a continuation of the debate on antiseptic surgery which had been adjourned at the last meeting. Previously to the reading of Mr. Holmes's paper, Sir Thomas Watson, Bart., and Dr. C. J. B. Williams, F.R.S., were nominated honorary members of the Society.

Mr. HOLMES read a paper "On a case of Ligature of the Femoral Artery with Carbolised Catgut for Popliteal Aneurism." Referring to the previous meeting, he said that in the discussion on the antiseptic method then introduced, the remarks of surgeons present indicated a great uniformity of opinion that the care in dressing, the cleanliness, avoidance of the introduction of foreign bodies, especially those of a putrefactive nature, constituted the great advantages of that method. Now there was no doubt that ligatures applied to vessels act as foreign bodies, and thus hinder the closure of the wound, and that silk ligatures especially imbibe septic matters; but it seemed to him that Sir James Simpson greatly exaggerated these evil effects, and laid too great a stress on the necessity of avoiding them when he was endeavouring to introduce the methods of torsion and acupressure. The catgut ligature was beneficial from the fact that it avoided these objections, and aided primary union. He would not, however, go into the subject of the use of this ligature on free surfaces, such as stumps, but only into its application in the continuity of vessels. He would not deny that catgut was not always absorbed, but that it was sometimes absorbed there could be no doubt. He had had no large experience in the use of catgut for tying large vessels in their continuity, but the case to be related would serve to evoke discussion, and elicit the opinion of surgeons on the subject. The use of the catgut ligature and of the carbolised catgut ligature were two different things. Sir Astley Cooper, Cradbourne, and Porta had all used the catgut ligature frequently with varying results. Sir A. Cooper's results were at first favourable; subsequent failures, however, induced him to give it up. Porta's experience was of a somewhat similar character. On the other hand, those who have used carbolised catgut claim to have obtained good results. Mr. Annandale states that its use removes all the ordinary dangers of ligature of arteries. Mr. Oliver Pemberton had also recently published a case in which the result was good, and had confidence in it without the use of antiseptic dressing, believing that it was a security against all ordinary risks. Mr. Holmes's experience was limited to four cases. In the first he tied the subclavian and the carotid for aortic aneurism; he tried to use antiseptic dressings, but the patient was too restless; the wound suppurated, but closed readily, and no part of the ligature came away. The man died eight weeks afterwards from the effects of galvano-puncture. The vessels were found to be closed only by a kind of diaphragm. Two minute pouches filled with blood-clot were found in the cellular tissue, outside the carotid, the coats of the vessel having been slightly cracked, but neither was divided, and there was no danger of secondary hæmorrhage. The third application of the ligature was in the case read to-day. It was of interest from the cause of death, the patient having died precisely seven days after the operation. The knot of the ligature was found, the rest was absorbed, and the vessel was not cut. In this case free suppuration occurred, although the wound was dressed antiseptically. The patient's death was due to extreme intoxication, and the suppuration doubtless owned the same cause. The fourth case was one of distal ligature of the left carotid for aortic aneurism, in which he tied the vessel twenty-two days ago with carbolised catgut, without the antiseptic dressing, simply covering the wound with cotton-wool after the operation. This was left some days undisturbed, but on removing it, some pain having been felt, pus was found pent up behind the wound, but at the present time it was not in an irritable condition. No trace of the ligature could be found. The results were inconclusive. In none of these cases was the antiseptic method used throughout; in those cases in which it was tried it did not succeed, in others it was not tried. The results were favourable in so far that secondary hæmorrhage was avoided, and union by first intention favoured, which is impossible with the silk ligature. He thought that carbolised catgut was proved to be useful in cases of aneurism, and that the good result was favoured by drainage and by Lister's method. The great disadvantage of Lister's plan was the amount of *moisture* necessitated in the operation. He did not see why washing the wound out after the operation with carbolised lotion, and thus eliminating any chance germs, should not do as well as using spray, &c., which confused the view of the parts, and made it necessary to disturb and pull them about more than was advisable.

The case was that of a man thirty-four years of age, footman to a nobleman, and no doubt of drinking habits, as discovered afterwards, who was admitted on June 9th with a small popliteal aneurism. He had had good health; no syphilitic history. Five days before admission he noticed a swelling of the left foot and ankle, having previously had aching pain, as if the knee were tired, for three weeks. The pain increased by sitting down or by extension of the leg. On admission he was pale and of delicate look. There was a small swelling in the lower part of the popliteal space; there was no bruit and no thrill, but expansile pulsation, rather as if there were a saccular dilatation than an aneurism. Slight pressure on the femoral sufficed to check the pulsation; flexion of the limb, which was tried, only increased the pulsation. Digital pressure was tried and carefully maintained by the students for twenty-two hours continuously; then, after an interval of twenty-four hours, it was kept up for six hours a day for three days; then pressure by a weight twelve hours a day for four days; and then digital compression again; then mechanical pressure was tried, but without success. Finally ligature of the femoral was performed on Aug. 12th with carbolised catgut. The wound went on well for four days, slight pain occurring for two or three days in the course of the saphena vein, a branch of which had been cut during the operation, but this soon subsided. On Aug. 15th Mr. Holmes left town, the patient then being in a good way; but returning on the 18th, was astonished to hear of his death. He had gone on well till the 16th, when a friend smuggled in two bottles of gin. In the evening he was found in a state of furious alcoholic delirium, having drunk one of the bottlesful. From that time he rapidly sank, being in a condition of high traumatic fever till his death. No post-mortem could be obtained, but the artery was taken out. The vessel was found to be continuous, and only the knot of the ligature remained; there was suppuration around it and in the groin. The aneurismal sac was filled with a dark coagulum, but in the rest of its course the vessel was healthy. There was no gangrene, but the integuments over the heel were observed to be hard, dry, and of dark colour. The wound had been dressed on the carbolic method under spray, although the latter was not used during the operation. There was no œdema, no swelling, and no tendency to suppuration.

Mr. Holmes stated that he was unwilling to operate on account of the small size of the aneurism and its quiescence so long as the patient kept in bed, but the pain in walking and other symptoms led to the belief that a serious result would ultimately ensue. Esmarch's bandage had not been tried; if he had seen a recent paper on its use in these cases, he would certainly have given it a trial. No irritation was set up by the catgut ligature about the artery; the condition was quite different from that seen in ordinary ligature. But for the drinking, he believed it would have been absorbed, and the artery obliterated without any bad result.

Mr. CALLENDER said that the subject before the Society was one of importance to all practical surgeons, involving as it did the whole question of ligature of an artery in its continuity in cases of aneurism. The question raised by Mr. Holmes was how far carbolised catgut was applicable for ligature in such cases.

Mr. MAUNDER said that he had had some experience of the ligature of arteries in their continuity, having done it in twenty-seven cases. Of these the antiseptic ligature was employed on nine occasions, but catgut only five times. He would, therefore, confine his remarks to these five. The first two were ligature of the brachial, which was done in two cases for hæmorrhage from the hand; in these two the wounds both suppurated. One was in the hospital a long time, with the wound suppurating, and recovered, and the other died of pyæmia; in the latter the inner coats of the vessel were found to be divided, a clot was found on the distal side of the ligature, but none on the proximal. No ligature was found, the patient having died on the tenth day. In two other cases he had tied the femoral for popliteal aneurism; of these one was a spare man, thirty years of age, in whom he tied the vessel at the bottom of Scarpa's triangle, and primary union occurred in a few days. The man died six months later of internal aneurism. The second case was of a man forty years old, with much subcutaneous fat, ligatured in the same way. In this case he did not use the spray, as it frightened him, but carbolised water was used as a lotion, and his fingers and those of his assistants were dipped in the same. There was free suppuration of the wound for some time, but ultimate recovery. It was curious that these results should be in such contrast. The fifth case was one of ligature of the subclavian for axillary aneurism, carbolised catgut being used, but not the spray. He allowed Mr. Cooper to use antiseptics after the operation. The patient died on the sixth day with diffuse suppuration in the chest. In only one case, therefore, out of five, did primary union occur, and he believed that in that case it would have occurred independently of the carbolised catgut. In other cases silk was used, one after Lister's method, and in that the wound healed in ten days almost by first intention. The specimen was shown recently at his Lettsomian Lectures; the ligature was found still on the vessel. He had also used it in two other cases of aneurism. Hitherto he had used carbolic acid with good success, and he should continue to use it until some unfortunate accident, such as had occurred to other surgeons, led him to give it up. Mr. Holmes's results could not be considered successful. In answer to subsequent inquiries, Mr. Maunder stated that in the first case of ligature of femoral the ligature was not found, but the vessel was obliterated as far as the popliteal. In the case of subclavian ligature, the ligature remained on the vessel, which was occluded.

Mr. BARWELL remarked that the question seemed to be, Will the catgut ligature melt away and be absorbed? He had seen a case in which this had occurred. The fact of free suppuration in Mr. Maunder's cases was not at all derogatory to the merits of the carbolised catgut ligature. He himself had used the catgut ligature many times in the face of stumps, but in only one case did it come away with the discharge. As to the ligature of arteries in their continuity, he had tied the radial and brachial and both facial, making in all four such operations. Both the facials were tied in a case, exhibited to the Society last year, of hypertrophy of the lower part of the face; in that case each artery was ligatured in two places, and the vessel cut between. Although there was a severe attack of erysipelas, the wound only suppurated slightly, and no ligature came away. In the case of the brachial the wound suppurated; in that of the radial it healed by first intention. But the fact of suppuration occurring did not affect the question of ligature by catgut. If we could avoid cutting through the artery, and the occurrence of secondary hæmorrhage, and more especially of suppuration around the vein, the advantages gained would be sufficient. One practical point of importance was, that the catgut should not be allowed to get dry before the operation.

Mr. MYERS gave his experience in the most important case he had treated in this way,—that of a man who had aneurism of the external iliac artery. After all other means had failed, he ligatured the external iliac, putting on two ligatures, and then closed the wound; there was considerable suppuration, though not from the effects of the ligature. The man did well and was cured, and is now doing duty in his regiment. The ligature did not come away with the discharge, and the suppuration appeared to be due to the fact that the man was syphilitic and an unhealthy subject.

Mr. GASCOYEN said he had seen three cases in addition to the one just related by Mr. Myers. Two of them were of the femoral, one of the brachial. One of the cases of femoral did badly; it was that of a girl in the Lock Hospital, under the care of Mr. Lane, in whom the vessel was exposed by a sloughing bubo. There was severe inflammation and secondary hæmorrhage, which was twice repeated, and proved fatal on the second attack. No ligature was found on the tenth day. Of two other cases, one was of hæmorrhage from a popliteal aneurism in a heavy drinker. Here the femoral was tied with catgut, using all precautions, but without the use of antiseptics. The wound remained open for six weeks, a part of it uniting by first intention, but a small sinus being left, from which at last something came away, and the wound healed. The other case was one of popliteal aneurism, in which the femoral was tied, the subsequent course resembling that of the previous case, something coming away at the end of six weeks. He did not think that this something was the ligature, but a sloughing caused by the bruising of the external coat of the artery.

Mr. MARCUS BECK observed that in nearly all the cases which had been mentioned in the discussion the result was that the wound was not in any more favourable condition than it was under the old method; but seeing that the whole of the details of Lister's method of dressing were systematically neglected, this was not surprising, and it was not fair to consider these cases as having any relation to Lister's method. Lister had always held and stated that in a few hours after the ligature there was no trace of carbolic acid left in the wound, and hence there could be no reason why suppuration should not occur. The catgut ligature was as ready to decompose as any other substance, so that probably the result in most cases was that it decomposed and the artery sloughed, the result being the same as with the ordinary ligature. He had not had any experience of ligature of vessels in their continuity, but in cases where vessels were tied in a wound treated antiseptically the result was good; there was no suppuration and no discharge. But he should not suppose that it was of any use when employed in other ways. As to the question of the ligature melting away, he had seen a case in which, after six or seven days, the ligature remained intact. But if the wound were treated in the ordinary way, the mass of putrid catgut in the wound would set up suppuration. Lister had not had any case of secondary hæmorrhage among his cases.

Dr. MURCHISON remarked that he did not understand that Mr. Holmes had brought forward his case at all with the object of discussing the antiseptic system. He believed it was a well-known fact that Syme ligatured the femoral twenty-five times in succession, using the ordinary silk ligature, without antiseptics, and every one of the cases did well; he had no bad result. He had himself assisted Syme in one of these operations.

Mr. HERBERT PAGE said he had only had occasion to tie the femoral in its continuity on one occasion, and then he made no attempt to use the catgut ligature; there was free suppuration, but the result was good. He had used catgut in other cases, but he questioned whether it was not rather the way in which the vessel was tied than the material used which affected the result; quoting a saying of Prof. Humphry's, that secondary hæmorrhage was usually due to the fault of the surgeon. If he was not mistaken, Lister said that the catgut yielded very soon.

Mr. CHRISTOPHER HEATH thought that it was obvious from the remarks made by previous speakers that the catgut ligature behaved differently under different circumstances, and probably this was due to the difference of the surgeons. In the first place, the amount of force to be used is difficult to judge, on account of the elastic and yielding nature of the catgut. The source of the secondary hæmorrhage was, probably, that the artery was cut. In the first case in which he employed it, one of ligature of the carotid for aneurism of the aorta, three years ago, the patient was still living and in good health. After the ligature the wound was closed with cotton-wool, and at the end of a week it closed. The second case was one of secondary hæmorrhage after amputation, for which the femoral was tied in Hunter's canal, on account of the risk of moving a tourniquet; suppuration followed, and the patient died seven days afterwards. The ligature was found *in situ*, and there was clot on both sides of it. The condition of the patient had probably much to do with the result of the operation, especially as to the occurrence of suppuration. He had twice, since this, used this method of ligature; once on the carotid for aortic aneurism, the patient dying on the same day from the immediate effects in the brain. The last case was one of femoral aneurism in a medical man who was present. In that case, pressure having only the effect of reducing the health, the vessel was tied; free suppuration occurred, but the wound healed, except in a small track, from which something came away at the end of eighty-two days. This operation was in February last, and the aneurism, which was of moderate size, had quite disappeared.

Mr. Maunder, in reference to previous remarks, said that the nine arteries were all tied on Lister's method, with the exception of the use of the spray; and as to some of the cases which occurred in 1868, the spray was not introduced at the time. If spray was needless then, why should its use be so necessary now?

Mr. Beck replied that in 1868 Lister's method was not nearly perfected. He saw and took notes of cases in Mr. Lister's wards in Glasgow in 1868, and the number of successes was much smaller and the dressings much more clumsy than now. At that time, in Mr. Lister's own practice, decomposition was prevented in only 30 per cent. of the cases.

Mr. Macnamara had not had large experience in the method, having only used it in four cases. In one case of ligature of the brachial with Lister's method of dressing there was no suppuration, and a good result followed. The second case was one of the carotid and subclavian for aneurism, which did well till the tenth day, when there was sudden hæmorrhage and the patient died. The third, one of the femoral for wound, the antiseptic system being thoroughly employed, did well; there was no suppuration, and recovery was rapid. In the fourth, a case already published in The Lancet and in the *Indian Medical Gazette*, the antiseptic system was not fully carried out, but the patient did well. In these cases, he thought, it was important to attend to the mode of preparation of the catgut, which, if left long in carbolised oil, was apt to get brittle and less elastic. It should be kept in cod-liver or some other fish oil.

Mr. Holmes, in reply to Mr. Beck, said that he had endeavoured to state clearly that he was not talking of Lister's method. In the first case Lister's treatment was used, but its application was not maintained, and in the second the extreme intoxication and restlessness of the patient prevented its success; in the third it was not tried. He fully agreed with Mr. Beck as to the fact that antiseptic dressing was preferable to the ordinary method. He also believed, with Mr. Barwell, that the question of suppuration or non-suppuration was less important than the mode of ligature of the vessel. There were cases on record where the catgut ligature had melted away and secondary hæmorrhage resulted, but he believed that ligature with catgut was quite possible to do successfully.

Mr. Callender, in remarking upon Mr. Holmes's case, observed that Mr. Holmes wished only to bring before the Society the use of catgut ligature. The condition of wounds, when treated by Lister's method, was quite a different matter. For his own part he had every reason to be satisfied with the results obtained by his own method, which was enough for all ordinary purposes, and sufficed to ensure healing. He wished, however, to go into the question of the use of the carbolised catgut ligature. Three instances of secondary hæmorrhage had followed its use in St. Bartholomew's, two in the practice of his colleagues and the third in his own. In this case, which was very carefully observed, the patient was a young man of good habits, the only unfavourable fact being that he had slight atheroma, as was seen after death. The femoral was ligatured at the bottom of Scarpa's triangle for aneurism, the carbolised catgut ligature being employed to tie the vessel and also to drain the wound. On the fifth day, at the 130th hour, slight pulsation was felt in the artery and in the aneurism. At the 156th hour the carbolised catgut used for drainage came away in two pieces, having softened in the centre. On the tenth day there was a gush of blood from the wound. The thigh was immediately amputated; but the patient died of the hæmorrhage and shock. On examining the limb the ligature was not to be seen, and the artery was patent; but in the wall of the vessel was an opening about one-sixteenth of an inch in diameter, through which the hæmorrhage had taken place. In this case the ligature had yielded at the 130th hour; but it had produced such an effect upon the artery that the vessel sloughed. The wound had healed well. He brought the case forward only in connexion with Mr. Holmes's case, and as showing the trouble which might occur from a reliance on this method of ligature.

Mr. Hart inquired whether the instrumental pressure mentioned by Mr. Holmes was performed under the influence of chloroform or not. He thought this was a question quite as useful to discuss as that of the catgut ligature. He knew of no case where such pressure, applied under chloroform, had failed; and as we have given up the idea of stratification being needed, we need not fear immediate coagulation.

Mr. Holmes replied that, as there was complete absence of pulsation on pressure by the means employed, there could be no reason for subjecting the patient to the additional risks of chloroform.

The meeting then adjourned, the debate having come to an end.

MEDICAL SOCIETY OF LONDON.

At an ordinary meeting of this Society on Nov. 8th, Dr. Routh, President, in the chair, Mr. Spencer Watson brought forward a patient, a young woman aged twenty-two, who had been treated jointly by himself and Mr. Carr Jackson for Compound Comminuted Fracture of the Os Calcis and Dislocation of the Scaphoid, the injury being the result of a gas explosion. The astragalus and a portion of the os calcis were excised, and the patient has now a useful and moveable joint, the limb being only shortened an inch and a quarter. The discussion on this case was postponed to the next meeting, in order to give time for Mr. Jabez Hogg's paper on "Spinal Concussion."

On the 15th inst. the proceedings opened by the discussion of the cases brought forward by Mr. Spencer Watson at the previous meeting.—Mr. Carr Jackson related two cases of his own, and dilated on the *pros* and *cons* of excision of the astragalus, as compared with amputation of the foot.—Mr. Royes Bell spoke of a case of Mr. John Wood's at King's College Hospital, in which excision of the astragalus had been performed, and which had done well.—Mr. W. Adams remarked that Mr. Lund, of Manchester, had recommended this operation for club-foot; after which Mr. Henry Smith recounted the case of a lad who had fallen against an iron body, and who had been brought to him with an induration in the thigh. An abscess formed, which was opened, but the wound did not heal, and subsequently a piece of the boy's trouser was extracted.—Mr. Spencer Watson supplemented Mr. Smith's case by the relation of three instances of impaction of a foreign body.

Dr. Drysdale then read a paper entitled "For and against Animal Vaccination." He considered that in all countries where vaccination was compulsory it might be as well for the process of animal vaccination to be added to that adopted by the State, and believed it would be an enormous advantage in sudden emergencies.—An animated discussion followed.—Mr. de Méric questioned if animal vaccination was more to be trusted than the ordinary process. He recounted at some length the experiments on animal vaccination he had witnessed in Paris, which had much impressed him with regard to its facility. He had no doubt at all that syphilis can be propagated by vaccination.

He suggested that the two modes could very well be in vogue at the same time, but thought that the introduction of animal vaccination in this country required the co-operation of the Government, as it had been tried by private enterprise and had failed.—Dr. Theodore Williams thought animal vaccination would be of great use in an epidemic, as he remembered the difficulty of getting lymph during the last one.—Dr. Cook had heard animal vaccination deprecated some years ago as exciting too great constitutional disturbance.—Dr. Griffith thought syphilis could not always be detected in a child by the most minute examination, and related a case in point.—Dr. Rogers, in thirty-five years' experience, had only seen one bad case as the result of vaccination. He mentioned the strong public feeling against vaccination, and thought animal vaccination would be a great boon if accepted by those who object to the other.—After Dr. Drysdale had briefly replied, Dr. Dowse exhibited a Kidney having the semblance of a large cyst, taken from a patient who had died from disease of the brain.—The meeting then adjourned.

ENTERIC FEVER AT CROYDON.

Croydon at the present time is suffering from a widely extended outbreak of enteric fever. In the spring of the year fever made its appearance in the town, and a considerable number of persons were then affected by it; this epidemic declined during the summer months, but at no time since last April has the town been completely free from fever. Suddenly, about the first week in October, there was an increase in the number of cases, and the disease also made its appearance in the districts of Selhurst and South Norwood, which previously had been almost if not entirely free from the disease. The number of persons attacked during the last few weeks amount to between 300 or 400. The inhabitants residing in the upper part of the town having suffered most severely, the medical officer of health for the town and district, Dr. Philpot, has been busily engaged in investigating the causes which led to the outbreak, and ascertaining how far the limits of the present epidemic coincide with those of the first; the information on the latter point is not yet complete. Dr. Philpot considers that "the suddenness of the outbreak over a wide area is strong *prima facie* evidence that water is the conveyor of the disease," especially as the fever has "occurred in houses the interior of which have no connexion with the sewers." And in this opinion, after a careful consideration of the facts connected with the outbreak, we entirely agree with him.

A water-supply may become contaminated at four points: at its source, in its storage, in its delivery through the mains, and, finally, in the houses of consumers. No suspicion seems to have fallen on the purity of the water as taken from the springs, but the blame is distributed between the storage arrangements at the reservoir and the intermittent nature of the supply. The water at Croydon is stored in two reservoirs: one the low-level reservoir, and which originally sufficed for the requirements of the whole town; and the other the high-level reservoir, which was constructed at the summit of the water-tower, in order to furnish a supply of water to the tops of houses in the higher parts of the town. It is in the districts supplied by this reservoir that the majority of the cases have occurred. It has been suggested that the water contained in this tank has become contaminated through the overflow-pipe, which communicated directly with the sewer, getting untrapped, and consequently the sewer gases of the town have had access to the water-supply. Although no doubt such an arrangement is one of considerable danger, we do not think it sufficient in itself to have produced the epidemic in question, and we think the chief blame will be found, on further inquiry, to lie in a defective condition of the mains and the intermittent nature of the supply. It appears that, from want of sufficient water, the supply is still occasionally intermittent in the low-level; in the high-level the supply is more constant; but it happened that there was an intermission of some hours on the 16th of September, about fourteen days before the large increase in the fever cases occurred. At that time the sewers, it must be remembered, must have contained specifically contaminated excreta from previous cases which had been occurring in the town during the summer months, and it is not unreasonable to suppose that the strong suction action that was going on within the mains on that day may have drawn the specifically contaminated contents of the neighbouring sewers into them, to be distributed wholesale the next time the mains were charged. The two great epidemics of last year—viz., at Over Darwen and Lewes—originated in this way. At Over Darwen the typhoid excreta found their way from the privy of a house in the outskirts of the town to the water mains, into which they were sucked during the periods of intermittency, and the epidemic continued till this source of infection was discovered. At Lewes the first outbreak was traced to distinct pollution of the water at its source. The second outbreak, occurring shortly afterwards, was caused by the contents of a sewer charged with stools of the patients who had suffered during the first outbreak being sucked into a closely adjacent water-main, likewise during a period of intermittency in the supply. At Lewes, as at Croydon, it was the upper part of the town which suffered most severely. Wherever the water-supply is intermittent such a mishap is likely to occur; for it is not in the nature of either sewers or water-mains to remain for ever impervious, and sooner or later leakage is sure to take place. It is, of course, unlucky if both main and sewer chance to be defective at the same point, for then, unless the water-supply is kept at constant pressure, and the water-pipes fully charged, the contents of the sewer must be drawn into the mains. The sanitary arrangements of the houses, even of the better class, at Croydon seem extremely defective, and several of the houses have screw taps to the waterclosets—an element of considerable danger, as leading to local intercommunication between the contents of the sewers and the water-service of the house. With respect to the management of the epidemic, we strongly urge the local board of health to adopt the chief recommendations of their medical officer—to furnish the town without delay with a constant water-supply, and to make a diligent search for all possible sources of pollution.

AFFAIRS IN GLASGOW.

To the Editor of The Lancet.

Sir,—Would you have the goodness to permit me to correct your Glasgow correspondent in reference to one point in his account of the dispute between the Local Authority of Glasgow and the managers of the Royal Infirmary. He states that a "somewhat personal and hasty correspondence in the daily papers took place between the superintendent of the infirmary and Dr. Russell." The fact is, I have never written a line to the "daily papers" on the subject, or directly or indirectly taken any part in the controversy, excepting officially through the minutes of the Local Authority. Had the "superintendent of the infirmary" followed the same excellent rule, the controversy would either never have arisen, or been settled long ago in an impersonal, official way.

I am, Sir, your obedient servant,

James B. Russell, M.D.,
Medical Officer.

Glasgow, Nov. 15th, 1875.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 20, 1875.

The elaborate scheme drawn up by Mr. John Marshall for the institution of compulsory examination in Anatomy at the end of the first winter session, which was brought before the notice of the members of the Council of the College of Surgeons on the 11th inst., is a satisfactory sign of improvement and advancement. The spirit by which Mr. Marshall has evidently been actuated in making this proposal, and the interest taken in it by almost every member of the Council, are deserving of commendation, inasmuch as they show that there is some disposition on the part of the present Council to adapt itself and the College to the exigencies and requirements of modern times. The objects aimed at by Mr. Marshall are, of course, that the instruction in Anatomy shall be based on thoroughly sound principles, and that the knowledge acquired by students shall be not only useful but permanent.

It would have been surprising if Mr. Marshall, who has enjoyed rare opportunities of observing and testing the various methods of medical education and of estimating their results, had, when made a member of the Court of Examiners at the Royal College of Surgeons, failed to be struck with the anomalous state of the College examinations, especially the Primary. That he would, when fairly settled down to work as an examiner and a member of the Council, devise some valuable scheme for the amelioration of the College examinations might have been safely predicated. The anticipation has been realised in the memorandum that was laid before the Council at their last meeting.

As was announced last week, a Committee has been appointed to discuss the proposed measure in all its relations and bearings, and to report on it to the Council. What the decision of this Committee will be we cannot say. It may, however, be conjectured that, although the principle of the scheme will probably be recognised and accepted, the details will be considerably modified. Many objections to the adoption of the measure in its entirety have already been offered, and others will be sure to arise.

The principle of the scheme is briefly as follows:—

Mr. Marshall starts with the statement that under the existing system many candidates are rejected at the Primary Examination for the membership of the College; and he then alleges that, of those who present themselves, some pass extremely well, some barely succeed, whilst the remainder are so deficient in knowledge, especially of Anatomy, that they have to be referred for further study, though they have arrived at least at the end of their second year. And after all, Mr. Marshall adds in his memorandum, it has been recognised by those who conduct or watch the Pass Examination for the membership that a very large proportion of candidates retain a quite insufficient knowledge of Anatomy, often forgetting even the most simple and essential facts in that science. From these circumstances he correctly infers that the present results are not satisfactory, and that they point to the necessity of inquiry and improvement. So far most persons will agree with Mr. Marshall, but at this point many will stop, or at least part company. Mr. Marshall henceforth pursues a less certain course. He assumes that the cause of the failures at the Primary Examination at the College may be attributed solely and entirely to the students or teachers. In this he is somewhat opposed to facts. Mr. Marshall has been long enough a member of the Court of Examiners of the College of Surgeons to have noticed that, up to within a very short time, the unsatisfactory state of the College examinations has been as much due to the examiners as to the want of knowledge in the students. Many of the best students at the medical schools—medalists, honours men in Anatomy and Physiology—have been rejected at the College. Anyone who is at all acquainted with the previous training and experience of the examiners could point out several of the members of the Court who should never have taken office—at least, should never have been appointed to examine in Anatomy and Physiology. Even the Council has recognised this, and has at last consented to the appointment of special and competent examiners in Anatomy and Physiology. It is true that a little improvement has taken place within the last twelve or eighteen months, but it is too early to draw any conclusions from the results of the examinations as conducted by the present examiners. Mr. Marshall must therefore have based his opinion on the results of examinations two or three years ago, and in this he has fallen into error. In the third section of the memorandum Mr. Marshall expresses a doubt whether it is possible for any but vigorous and well-trained minds to acquire a reasonable knowledge of Anatomy in the two years now allowed for the study of that subject. Yet, notwithstanding this, the very aim of Mr. Marshall's proposal is to ensure that this reasonable amount of knowledge shall be acquired by every student. Mr. Marshall appears to have misjudged the object of the medical student's education. It is of course impossible for any man, even for the vigorous and well trained, to become skilled anatomists like Mr. Marshall in two years, and this is neither necessary nor desirable. The aim of the medical student is to qualify himself for medical practice; and desirable as an intimate acquaintance with anatomy may be, it cannot be said to be of essential importance to practitioners of medicine, who may be very successful with a good general knowledge of the subject. In the same section Mr. Marshall has gone rather wide of the mark when he contrasts unfavourably the medical students of the present day with those of former times. He says that "those who first enter upon their studies *now* are younger than their predecessors were when they began attendance upon anatomical lectures and to work in the dissecting-room; their minds are less formed, less ripe for and bent upon thoroughly practical and efficacious study, less able or likely to appreciate the value of time, the pressure of their coming future, and the fact that opportunity lost is not to be regained." Mr. Marshall cannot be serious when he contends that, under the old system of apprenticeship—when boys were taken from school before they had acquired a respectable amount of preliminary education, and made for three or four years to do the uninteresting work and too often the menial drudgery of a country practitioner's dispensary,—better trained men entered the medical schools than in these days, when students generally pass direct from the strict training and discipline of school or college to the study of anatomy and physiology.

Notwithstanding the objections that might be raised to Mr. Marshall's argument, the question to be considered by those who are interested in the improvement of medical education is whether it would be well to institute *a compulsory and authoritative elementary examination in Anatomy at the end of the first winter session,* or immediately at the commencement of the succeeding summer session. Plausible as such a proposal at first sight appears, it will on closer investigation be found to be not altogether free from error and serious evils. If Mr. Marshall were content to suggest that such an examination as that to which he refers would be desirable, or that students if they wish to present themselves for examination at the end of their first year have the opportunity of doing so, or, still better, if the elementary examinations were made compulsory at the medical schools instead of at the College, we should at once say, so let it be. But to make the examination compulsory at the College would be one of the surest means to defeat the object it would have in view. If all men's minds and dispositions were alike, if the aspirations of all were similar, such an examination might have some justification; whereas, if every student who is desirous of becoming a Member or Fellow were compelled to pass an examination in Anatomy at the end of the first winter session, a very serious blow would be given to the higher aspirations of many of the better-class students. Many young men who enter the medical schools are not obliged to complete their student career in the brief space of four years usually allotted, but are prepared to devote a much longer time to their education. They may wish, for example, to employ their first year in the study of chemistry and allied subjects, which, if not taken up in the first year, must perhaps be passed by for ever; or, what very frequently happens, those who enter as medical students may wish to devote their first year to the preparation for such tests as the Preliminary Scientific Examination of the University of London. It would be manifestly unjust to thwart the ambition of such by compelling them to pass an examination in Anatomy at the end of the first winter session, merely to ensure diligence and industry on the part of dull or idle students; for it is for them that Mr. Marshall would legislate. Besides, mere inquisitorial examinations by licensing bodies are unsound in principle, and should not be unnecessarily multiplied. Students have already many terrors to impede their course, and are seriously hampered in their efforts by the multiplicity of regulations. To add one whit to the labours of the medical students would be both unjust and unwise. The most that should be done is to afford to students who do not intend taking any other qualification than that of the Colleges of Physicians or Surgeons the opportunity of presenting themselves for the elementary examination at the end of the first year, if they wish it, the result of this examination being made to tell on the second examination in Anatomy and Physiology, as Mr. Marshall has suggested. It is certain that if such an examination were found to be productive of good results, the vast majority of the worthy students would present themselves voluntarily.

Successive telegrams from India would appear to indicate that the progress of the Prince of Wales in that country may be much impeded and his route probably considerably modified by the prevalence of cholera in some of the districts that it was proposed he should traverse. Scarcely had his Royal Highness passed beyond the precincts of Bombay before anxieties awakened by this fatal disorder became manifest in the telegrams transmitted homewards from day to day for the daily press. It is hardly likely that these anxieties will become less as he advances onwards into the endemic area of the malady, although here, as in other parts of India, his visit has been timed to fall, as far as practicable, within the period when the disease is commonly least active. The grave responsibility which rests upon the Indian Government in this matter should awaken clearer conceptions of what is required from it in reference to cholera and allied subjects. By an unhappy coincidence, the Prince of Wales's visit to India occurs at a time when men's minds have been largely unsettled there in regard to the conditions governing the prevalence of cholera, when it is gravely argued that the accumulated experience alike of India and of Europe respecting these conditions must be set wholly aside, and when vague sanitary generalities are being substituted for measures of prevention based on an intelligent appreciation of the modes actual and probable in which cholera becomes mischievous. It might have been imagined that issues so important would have aroused the serious attention of the India Office, and have induced it attentively to consider what sort of reason or unreason existed for raising them. But it contented itself with reproducing them in its annual sanitary blue-book, higgledy-piggledy with admiring comments of its own, and certain criticisms of the Army Sanitary Commission, admirably adapted still further to unsettle Indian thought on the subject. It gave no heed to the fact that if the Army Sanitary Commission was right the new propaganda was utterly and hopelessly wrong, and that if the latter was right the former must be irretrievably in error; or, if it gave heed, it must have contented itself with certain amiable platitudes of the Commission respecting the propaganda which should, apart from other obvious considerations, have suggested the probability that both were widely astray. It might have been supposed, when the Commission showed that the so-called facts upon which the propaganda raised its issues were, as to chronology, inaccurate, and, as to local conditions, so shamefully imperfect as to render it impossible for the Commission to exercise its proper function of expressing an opinion upon the practical sanitary works needed, that the India Office and the Commission alike must have seen the impropriety and mischievousness of giving any weight to what must necessarily be the crude speculations of the propaganda. But no such thing.

Data which the Commission had shown would have been a discredit to the least intelligent inspector of nuisances, are assumed by it to be sufficient for gauging certain of the profoundest questions of etiology, and for justifying doubts upon some of the most elaborate results of modern European research, the India Office virtually assenting! Nor could it well be otherwise, when the ultimate reference of the India Office in these matters is a mixed Commission of military men, engineers, and medical men, which does not include a single person who is versed in modern etiological science. Such a state of things is in the highest degree discreditable to the India Office, and detrimental to the progress of etiological research and sanitary work in India. Such work has only been successful in proportion as it has followed the strict methods of inquiry and practice in this country. But the new propaganda, neither in language nor in method, has anything in common with etiological research in Europe. It uses a language which is a tissue of fallacies; it follows a method which compasses in a few weeks, among populations of various languages counted by millions, inquiries which here, with populations counted by hundreds or thousands, having a common language and every facility for information, occupy many months. Yet the India Office has no specially appointed and sufficient means of enabling it to judge rightly of such matters, separating chaff from wheat, and at all times appears to have a curiously imperfect knowledge of European research.

If the visit of the Prince of WALES to India should awaken at the India Office a true insight into the requirements of etiological research and sanitary practice, this will not be the least of the benefits which will flow from it.

◆

THE debate at the Clinical Society on Antiseptic Surgery has come to a conclusion, and we may well inquire what has been the practical result gained, and what will be its outcome as regards the employment of the system in the surgical practice of the metropolis? There were many points on which light might have been thrown by the debate, and we anticipated that some new testimony for or against the system advocated by Professor LISTER would have been forthcoming. It would have been expected that the results of a trial of LISTER's method in a rigorous and scientific manner would have been contrasted with the results of the ordinary methods similarly tried; that we should have heard whether and to what extent antiseptics may be trusted to prevent suppuration, decomposition, and traumatic fever; and that a comparison of different antiseptic materials would have been instituted. But when we look at the course of the debate we find but little of all this, and what there is requires some labour to extract from the mass of irrelevant matter surrounding it.

It may indeed be a matter for question whether there has really been a discussion on the antiseptic method of dressing. It will be remembered that the debate was raised on papers by Mr. CALLENDER and Mr. PICK on cases treated with various antiseptics. The case brought forward by Mr. PICK was regarded by some as one hardly suited for the purpose, but, such as it was, it served the end of raising a discussion. Mr. CALLENDER's cases were perhaps more to the point as an inquiry into the value of salicylic as compared with carbolic acid. His paper, however, received little or no consideration from this point of view, and was lost for the purpose of discussion. The debate on these papers, continued at the meeting on Oct. 22nd, was then formally adjourned until the meeting last Friday, when, it was stated, a paper would be brought forward on the same subject. It must therefore have been a matter of surprise to some and of disappointment to others to find that the antiseptic method was not to be discussed in its entirety, but that a subject which only bore indirectly upon it was introduced. It was obvious that the subject matter of Mr. HOLMES's paper had been misunderstood, and an interpretation put upon its title which was disclaimed by the author himself. Yet the error would readily have been rectified had not the Chairman, in introducing the discussion, pointed out an entirely different subject—viz., that of the best method of ligaturing large arteries in their continuity—as the topic for consideration. Thus the course of the debate was, as if by accident, shunted on to a wrong line, and a new matter introduced; and that this was so was shown by the fact that the speakers were nearly the same as those at the previous meeting.

We sympathise with those advocates of LISTER's method who would have wished to discuss the general question and to state their own views upon it, and with those who would have been glad to hear their opinions. There was an uncomfortable feeling evinced by some speakers that the antiseptic method must somehow be brought in, and hence some curious attempts were made to piece together two totally divergent subjects. And it scarcely needed the formal protest of an advocate of the method, or an equally formal disclaimer by the author of the paper, to show that the carbolised catgut ligature, apart from antiseptic dressing, can hardly be considered antiseptic. As was forcibly pointed out by Mr. BECK, the catgut soon loses its carbolic acid, and, when it has done so, is even more liable than the ordinary silk ligature to set up irritation and to become softened. And the cases mentioned by Mr. CALLENDER showed most clearly that such a result actually occurs. The defenders of LISTER's method may be induced to apply to their opponents the dictum of PASCAL—"*Incrédules, les plus crédules,*" and to say that, whilst refusing to allow the value of the free use of carbolic acid, they place unlimited faith in a minute quantity of the same.

What, then, is the outcome of the discussion? for to an attentive observer a verdict, none the less decisive because not formally expressed, has been given, and must to some extent influence the immediate future of the use of antiseptics in London hospital practice. And, first of all, it was evident that but few of the speakers either place faith in LISTER's theory or carry out his practice in full. It would be difficult to name more than one or two who are thoroughgoing believers in the theory, and there are scarcely more who strictly and fully carry out the practice. On the other hand, there were but few who did not express their belief in the utility of some portions of the method, especially in those which relate to the scrupulous care and cleanliness of wounds, and the avoidance of external sources of irritation or putrefaction. And if, as seems to be shown by the highly successful results of Professors SPENCE at Edinburgh and

Humphry at Cambridge, almost as much can be done by such precautions as by Lister's method, they have some ground for the assumption that the success of Lister's system is also due to similar causes. Granting this, however, it may fairly be urged that, apart from the theory, his method is at least one way of securing these benefits in the most efficient manner, as it enables the surgeon to be himself, to a great extent, the custodian of the wound; and it in nowise detracts from its value that other methods should rival it in this respect. After all, the test of experience is the test which is of real value in this as in all other questions of treatment; and until this has been applied by individual surgeons in a rigorous manner to a series of cases under varied conditions of hygiene and nursing, the arguments for and against the method on *a priori* grounds will be comparatively worthless. That such a scientific trial has not been made by most of the surgeons who took part in the debate was confessedly the case; some have tried it, but have given it up from weariness of the details, or dislike of the mechanical processes needed, and especially the disagreeableness of the spray during operations, and so have come to no conclusion of any value; whilst others have resented the insistance on a theory which they could not accept on the evidence given, and without which the practice seems tediously minute and even repulsive. It is yet open to the advocates of Lister's method, by bringing forward a series of cases, to show the superiority of results gained by it to those on other methods; and they may thus raise a discussion which will be of some value, if they care to do so. But with the present state of feeling on the subject, we question whether they would gain much by so doing.

One other point which was strikingly illustrated by this as by previous debates of a similar kind is the impossibility of a really scientific debate unless the questions to be considered be more clearly stated. The absence of a common and definite ground for discussion was evidently felt, and the last meeting resolved itself into a narration of experiences, many of which had little in common, and all of which would have been of far more value if connected with some expression of opinion on the more general question. Let us hope, even against experience, that this defect will be remedied in the next discussion of the kind.

◆

Dr. W. W. Johnston, one of the physicians of the Children's Hospital, Washington, has contributed a paper to the last number of *Hays's American Journal of the Medical Sciences*, containing observations that are not without practical significance and bearing at the present time, when typhoid fever is unduly prevalent. The author deals with the diagnosis of mild cases of enteric fever, and specially refers to its afebrile and abortive forms. The departures from the accepted type are in two directions: either in a loss of intensity of the morbid phenomena, with a feeble development or absence of the pathognomonic symptoms; or in a considerable shortening of the attack. Embarrassments of diagnosis will occur in such mild and short cases. Dr. Johnston passes in review the symptoms most commonly associated in cases of typhoid fever infection. Those whose experience of this disease is most extensive will be the readiest to recognise the wide range in point of severity and duration and the diversity of the morbid manifestations in different cases. Easy as it is to diagnose the well-marked type of the disease, it is not by any means invariably so in cases of different and less pronounced character. After insignificant symptoms perforation of the bowel may ensue, and the same may occur where diarrhœa has been absent; tympanites may not be present, or at any rate observed; and the intestinal disturbance and abdominal symptoms may, in short, be trifling or altogether absent. The same may be said of the rose rash, enlargement of the spleen, and other ordinary concomitants of typhoid. But as regards pyrexia—undoubtedly the most constant symptom of the disease, and the best test by which we can gauge the gravity as well as determine the nature of the morbid process,—can we say that every case of typhoid disease must of necessity present an increase of animal heat? Dr. Johnston cites the experience of Liebermeister and others to show that there is a typhoid infection without fever, and refers to the fact that in Basle, where typhoid fever prevails to a great extent, it is not uncommon to find an evident enlargement of Peyer's patches in persons who have died of other diseases or from accident. Cases may be reckoned mild which have no higher evening exacerbation than 104° Fahr., or in which this point is not attained more than once or twice. Starting from this we pass from degree to degree in the descending scale until we reach afebrile states; and the author relates some cases illustrative of these low-temperature readings where there was no reason to doubt that the patient's disease was still typhoid fever. He next refers to the so-called "abortive typhoid"—a term suggested by Lebert as applicable to cases first described by Griesinger, and since by Wünderlich, Jürgensen, and others. The typhoid infective agent has a virulence which is by no means the same under all circumstances, and the limits of variability are known to be very wide. In the same house, says Dr. Johnston, may exist cases which react in very different ways to an infection which seems to be the same; and he thinks that different cities and countries may probably present peculiarities, and it is for the future to determine in what these peculiarities consist. The points in which the typhoid fever of America differs from the European disease are briefly adverted to by our author. The practical lessons connected with the recognition and study of these varieties seem to be two:—First, that the mild cases, corresponding to the typhus ambulatorius, may receive prompt and proper treatment, so that the disease be not aggravated or protracted; and, secondly, that they be prevented from becoming unsuspected sources of infection to other and healthy people.

The *Pharmaceutical Journal* publishes a short paper by Dr. De Vrij, of the Hague, on "East India Chinchona Bark." The writer calls attention to the quantity of alkaloids which can be extracted from any variety of bark by water only. By percolating one part of finely-powdered Indian red bark with cold water until eight parts of clear fluid were collected, he obtained by precipitation with an excess of caustic soda three-eighths of the total amount of the alkaloids contained in the bark. Dr. De Vrij is engaged in prosecuting further experiments in this direction.

Annotations.

"Ne quid nimis."

THE VICE-CHANCELLOR'S ADDRESS AT CAMBRIDGE.

THERE are several points of interest in the recent address delivered by the Vice-Chancellor of the University of Cambridge (the Rev. Dr. Phear, Master of Emmanuel), at the close of his year of office, which are well deserving of notice and comment. The academic year which has just passed was one of great activity and prosperity in the University. The number of matriculations for the year was the largest yet recorded, and the number of primary degrees (B.A., LL.B., or M.B.) has been 477. Of these only about two-fifths graduated in honours. Dr. Phear remarked, however, that it is likely, as greater numbers come to the University, drawn from the less wealthy classes, the proportion of the undergraduates unprompted to active study will become smaller, and the social influences which encourage industry and simplicity of life will be strengthened. The changes on the professorial staff have been great: six elections into professorships have occurred within the year. The operations of the University have lately received extension by the establishment of examinations in the department of State Medicine. The number and character of the candidates for the first examination prove how highly the degree is estimated by the profession, and the public want it supplies. Another important movement has been placed on a permanent footing—the superintendence of lectures in populous places. The details of this scheme, when first discussed at a meeting at the Mansion House last summer, were noticed in our columns at that time, and we are now glad to learn that the University, after due consideration, has accepted the responsibility of maintaining and further promoting this system of local teaching, extending to a great degree the advantages of a University training to those at present beyond its reach. For some time past great inconvenience has been felt owing to the want of accommodation in the buildings set aside for special departments. The increased number of students working at chemistry, physiology, and comparative anatomy has made the demand for increased accommodation more urgent. We are glad, therefore, to learn that the report of the Additional Buildings Syndicate is now before the Senate, and that ere long the required accommodation will be provided. Whilst on the subject of additional buildings we would venture to suggest that some step might be taken to extend the residential accommodation for students. Most of the private colleges have recently added to their buildings, but they are quite unable to keep pace with the ever-increasing number of the undergraduates. The lodging-house accommodation is hardly sufficient, and men yearly have to seek for rooms further and further off from their college, in the outskirts of the town. Moreover, the sanitary arrangements of the lodging-houses are far inferior to those of the colleges. We think the University might with advantage undertake to provide blocks of buildings, in different parts of the town, to be let to responsible persons for the special accommodation of out-college students. Lastly, Dr. Phear remarks that no one intimate with the active work of the University can fail to be struck with the evident strain now put on the senior members in residence. Lectures, syndicates, examinations, &c., have increased immensely in number and scope of late years, and the tutorial staff consequently are overworked. Dr. Phear expressed a belief that the efficiency of the University depends on all natural inducements being provided to attract and retain the mature services of more of the ablest members. It certainly has always appeared somewhat anomalous that no less than one-third of the net income of the University should be expended on non-resident members. Every year fellowships are conferred on distinguished scholars, the majority of whom leave the University, drawing from it for years a considerable income without rendering in return one particle of service. The tutorial staff at the University sadly needs enlarging, and it is only fair that its revenues should be applied almost entirely for this purpose. A reduction in the number, value, and time of tenure of non-resident fellowships is urgently called for, and this is the direction in which University reform ought to tend.

DIPSOMANIA.

OUR contemporary, the *Globe*, whose useful efforts to promote the much-needed legislation upon this subject we have before noticed, has recently commented at some length upon the able article on the subject in the current number of the *Quarterly Review*. To the instances of the abuse of alcohol which cry with keenest if not with loudest voice for interference, the writer adds another. In addition to the prevalence of the vice among women, boys are yielding to the temptation. At an age when reflection sets so few barriers against wrong, the chains of alcohol may easily be riveted before their weight is felt. It is authoritatively stated that this is the case, and that the habit of secret drunkenness is becoming common among boys at public schools, to an extent which the friends of the sufferers would willingly conceal. It may be hoped that the case is exaggerated, but knowledge of the even worse habits sometimes acquired at public schools forbids us to doubt its probability. The dissemination of precocious vice has ever been an unhappy consequence of the example of the contaminating few in large schools. Readers of a popular school-boy novel of twenty years ago will remember how powerfully this result was brought out in the delineation of the downward moral course of certain boys. It cannot be doubted that the same influences are, and always will be, at work in this and in other directions.

Our contemporary urges a milder measure of interference than will, we believe, effectually meet the necessities of the case. It points out the striking anomaly to which we some time since called attention, by which habitual drunkenness is allowed and suicide forbidden, but it urges merely the legalisation of "voluntary restraint," if the expression may be excused. It asks for a measure which shall permit the dipsomaniac in his sober moments to place himself in a restraint which he shall not leave in his unsound period, and it would merely give power to others to enforce such seclusion in the case of minors. It would further, as far as we understand it, limit such seclusion to the unsound dipsomaniac, who is urged onward to his fate by what the *Quarterly Review* calls the *vis a tergo*, and would not include the habitual drunkard, who merely yields to a temptation which he might withstand. It may be doubted how far any line can be drawn between the two classes, except that of frequency of intoxication. The *vis a fronte* and the *vis a tergo*, the temptation and the impulse, are, in reality and essentially, one in nature. Their extreme degrees are separable, but they blend. The temptation often yielded to, involves, by the alcoholisation of the system, the incapacity for resistance which in its extreme form constitutes the impulse. Compulsory privation from alcohol lessens the attraction of the temptation as it lessens the force of the impulse. We believe that the larger measure must ultimately come, and we would urge that the demand should not be restricted to the smaller instalment, even though we may ultimately have to be content for a time with the "voluntary restraint."

THE "FACING" OF GREEN TEA.

THE 1st of January, 1876, will decide the question whether "faced" or painted tea is to be regarded by the law as adulterated. We have always held that the practice of facing was objectionable, not only because it is a fraud, though generally a small one, on the consumer, who pays for tea and not for paint, but also, and more particularly, because it affords facilities for adulteration with faded leaves, lie tea, &c. That facing is quite unnecessary is proved by the fact that much excellent tea, green as well as black, entirely unfaced, is now imported and used in England, and it is indeed impossible to assign any valid reason for the continuance of the practice.

The position of tea importers is at the present time a very delicate one, and we regret to find, from a recent correspondence published in *The Times*, that the Custom House authorities are unable, or unwilling, to afford them any assistance. A well-known firm of tea importers wrote to the Commissioners asking whether, after the 1st of January next, the importation of all faced tea would be prohibited, and, if not, what amount of colouring matter would be allowed. In a subsequent letter they offered to send samples of such tea as they were in the habit of importing for the examination of the analyst, and in both letters they pointed out with perfect truth that "no merchant would venture to import an article which might, at the caprice of an individual analyst, be condemned to be destroyed." To these representations the Commissioners replied in effect that no information of the kind required would be given, but when the Act came into operation each case that arose under it would be separately considered.

It seems clear that, whether the Commissioners have made up their minds to treat as adulterated all faced teas, or whether they intend to permit a certain amount of coloration, it is equally their duty to give timely notice, and so prevent unnecessary injury to trade. As things stand now, the merchant will have equal cause to complain if he imports slightly faced tea and has it seized and destroyed, or if, having himself stopped the importation, he finds that other cargoes of faced tea are allowed to pass. It is to be feared that the authorities have not yet made up their minds in the matter.

THE SANITARY CONDITION OF BRISTOL.

DURING the past month or two the mortality returns of Bristol have exhibited most of those signs which experience warns us not to disregard as evidence of unsatisfactory sanitary condition. The death-rate has considerably exceeded that which has prevailed in recent corresponding periods; the excess has, moreover, undoubtedly been due to an unusual fatality from zymotic disease. Scarlet fever has been remarkably fatal, and the deaths referred to small-pox, measles, whooping-cough, and enteric fever have also been above the average. A belief in the intimate relation that exists between sanitary condition and the fatality from zymotic disease appears to us essential to a hopeful view of future sanitary progress, and we therefore regret to see that, in his last quarterly report, the medical officer of health for Bristol, in speaking of the present epidemic of scarlet fever in the city, says:—"Observation leads me to believe that the great fatality of this disease is but slightly, if at all, dependent upon general sanitary conditions, remediable by a sanitary authority." Epidemic scarlet fever in Bristol, as in other localities, appears to have visited different parts of the city with a widely varying fatality. During the three months ending September last, the annual death-rate from scarlet fever was but 0·3 per 1000 in Clifton parish, whereas it was 2·8 in Bedminster, 4 in St. Paul, 6·4 in St. Philip and Jacob, and 8·1 in St. Mary Redcliffe registration subdistricts. In other words, the epidemic has visited most severely the crowded parts of the city, where even in ordinary seasons an excessive death-rate invariably prevails. To ignore the fact that these continuous high death-rates in certain parts of the city of Bristol, supplemented by excessive fatality from zymotic disease in epidemic seasons, are due to want of wholesome conditions, would augur badly for the future sanitary welfare of the city. Even epidemics may be turned to good account, as their fatality affords a valuable indication of the localities in which the population is living under circumstances unfavourable to health; and these circumstances are in most instances remediable, or may certainly be alleviated by sanitary measures, in accordance with recent legislative enactments. Bristol has till recently showed comparatively low death-rates, but the evidence that the city has in its midst more than one "unhealthy area" is too strong to be safely disregarded. It may be hoped that the Town Council will recognise its responsibility under the recent Artisans and Labourers' Dwellings Act, in the same manner as the sanitary authorities of so many of our other large towns have already done.

DENSITY OF POPULATION AND MORTALITY.

THAT death-rates in various districts almost invariably bear a distinct relation to their density of population is a well-known fact. If the 629 registration districts of England and Wales were arranged in the order of their density of population, calculated by the number of persons to each acre of their area, and against each district were written the average annual rate of mortality, say in the last completed decade—1861–70,—it would be found that their rates of mortality would run in almost unbroken order from considerably less than 17 to more than 30 per 1000 persons living. This apparently inseparable connexion between density of population and death-rates has had the somewhat mischievous tendency to create an impression in some quarters that, given density of population, a high death-rate is inevitable. The special report of the directors of the Improved Industrial Dwellings Company (Limited), recently considered at a meeting at the Mansion House, contains some valuable information showing that, with judicious economy of space and the due observance of sanitary laws, health and density of population are compatible. The above-mentioned company has, since it commenced operations, housed 12,150 persons in 2199 tenements in different parts of London. The average density of population on the area occupied by the improved dwellings is 750 persons per acre, whereas the average density in the whole metropolis is but 42 persons to the acre. Notwithstanding this great density, calculated by the acre, the average annual death-rate in the Company's dwellings during the past nine years is said to have been but 16 per 1000, against 23·8 in the whole of London. These figures appear to show that one of the direct results of the dwellings erected by this Company is an annual saving of more than 100 lives on the most moderate computation, as it may fairly be assumed that the rate of mortality in the districts from which the inhabitants of these dwellings have been drafted was considerably higher than the average rate in the whole of London. The problem of how many human beings can be housed upon an acre of land without detriment to health has not yet been solved, but this statement of the Improved Industrial Dwellings Company proves that some more satisfactory means than the number of persons per acre is wanted for estimating density of population in towns. A recently published paper dealing with the housing of the population of some of the larger American cities attempts to estimate the overcrowding in these cities by stating the number of persons to each inhabited house. For instance, it is stated that in New York, Brooklyn, and Jersey City there are more than 12 persons to each house, whereas the proportion in Philadelphia does not exceed 7½ persons per house. Unless the size of the houses be taken into account, these figures give no more reliable indication of overcrowding than does the statement that the residents in the Improved Industrial Dwellings average 750 persons per acre. The amount of cubic space in houses for each person is the only true test of density of population in towns, but, failing this, the area to each person of the rooms occupied, or even the number of persons to each room, would afford a far truer indication of density than either the persons to an acre or the persons to a house. So important is the bearing of overcrowding upon health, that it would be very desirable to see adopted some more correct measure of the density of population than those now generally used, which often give fallacious results.

A MEDDLESOME "PRIEST."

It is no doubt difficult for people with missions to restrain their enthusiasm within due limits. The very belief in a commission to obey some supreme behest or carry out a supernatural purpose places its possessor beyond, or, as he would say *above*, the constraining influences of mere worldly prudence. It does not seem to occur to individuals so gifted that the fervour of their enterprise is scarcely likely to be shared by those around them, and that this circumstance calls for increased carefulness and address on their own part to prevent their ministrations being productive of resentment rather than gratitude. They forget that the exceptional character of their position must needs awaken distrust in those who do not happen to be inspired with faith or confidence. The Rev. Mr. (or "Father") Brendon, of the Monastery at Gorton, Manchester, apparently labours under this form of forgetfulness. He is intensely in earnest and boundless in his zeal. His business is to save souls, and as he happens to hold the inconvenient doctrine that children enjoy an independent spiritual existence anterior to the accident of birth, he has no scruples about resorting to the expedients of science with a view to get at the bodies in which these little souls are encased, in order that they may be baptised and so brought into a state of salvation. No doubt a considerable number of persons share the belief cherished by the Rev. Mr. Brendon, and it is clearly competent for them to perform the rites proper to their convictions; but when the enthusiasm of a "priest" so far overmasters his sober sense of right and decency as to induce him to send for a surgeon and instruct him to perform the Cæsarean section on the body of a woman just dead, without even consulting the husband of the deceased and obtaining his permission, we venture to think he must be fired with a zeal calling for restraint. Of all forms of priestly interference in the affairs of families, that illustrated by the exploit of the Rev. Mr. Brendon, if not the most mischievous, is probably the first in audacity. We can conceive of nothing more effusively paternal. Not only the adult souls in this reverend gentleman's care are under his protectorship, but all that may be added to them, whether actually numbered among the inhabitants of this world of sin and sorrow, or only probably destined to enter its gloomy portals. It is, doubtless, too much to hope that the Rev. Mr. Brendon will attach any weight to the opinion expressed by the coroner's jury at Manchester. Possibly, however, the surgeon who acted as the priest's henchman in this matter, and other practitioners who may be allured or impressed into the same kind of service, will in future remember that it is necessary to obtain the consent of the responsible friends before operating even on a corpse, and that the law of England does not recognise the friendship of ghostly fathers as of a nature to give validity to their sanction. There is always a dash of comedy even in the deepest tragedy, and in the present case it appears to have taken the shape of a discovery that the babe in whose spiritual welfare the Rev. Mr. Brendon evinced so lively an interest, was in fact a fœtus of about the fourth month.

PLETHORA AT THE PATHOLOGICAL SOCIETY.

The profession is to be congratulated upon the increasing interest taken in pathological science, as evidenced by the large number of specimens which swell the list at the Pathological Society; but it may be doubted whether this state of congestion is altogether an unmixed good. It certainly cannot be regarded as such by those members who, with praiseworthy perseverance, bring down the same specimens to two or even three successive meetings before they are enabled to exhibit them. Exception is rightly made in the case of fresh specimens, which, as retaining their natural characters unaltered by preservative reagents, are always welcome. Yet it often happens that cases of great interest are postponed, and appear on the list on two or three occasions. At the last meeting of the Society, which we report to-day, the number of specimens down on the list read by the President at the commencement of the meeting was twenty-seven, and it says much for the expedition and conciseness of the communications that no fewer than seventeen of these were "worked off" in the ninety minutes. There remain ten still to be shown, so that it is unlikely that any additional specimens will come forward at the next meeting, which does not take place for three weeks. The contrast between the present meetings and those of the old days, when two or three cases sufficed for the whole evening, is striking, and is enough of itself to account for the more lengthy and interesting discussions that used frequently to take place in the past. It is doubtless the sense of the large amount of work before the Society that deters members from making comments on cases which are worthy of more notice than they receive. It is obvious, further, that the Society should strictly keep within its proper limits, and on this account it does not seem desirable to countenance the exhibition of specimens which are avowedly brought down merely to illustrate a particular line of treatment without any reference to pathology. It does occasionally, but not often, happen that pathology has thus to give way to clinical medicine or surgery; but surely in the present plethoric, but withal prosperous, condition of the Society, the introduction of extraneous matter should be as far as possible avoided.

LEPERS IN BOMBAY.

After reading the descriptions of the gorgeous displays, the festivities, and other manifestations of public rejoicing in the East with which the Prince of Wales has been welcomed in Bombay, it is indeed difficult to realise the terrible spectacle presented by a number of wretched human beings in another part of the same city. The *Times of India* draws attention to the state of the lepers who have found a refuge in the Jamsetjee Jejeebhoy Dhurrumsala—an institution founded for the relief of the sick and destitute, and not for lepers especially, although these poor wretches are only too glad to find a refuge there from the streets of the city. Such as it is, the Dhurrumsala is the only place of the kind open to them. About 120 are lodged in it at the present moment, and they share its scanty accommodation with nearly an equal number of the halt, the lame, the blind, and the aged. They live in what are termed chawls, each room, or rather cell, of which is about six feet deep by five in width, and so full is the institution that two lepers occupy one of these cells! The description of the unfortunate creatures given by our contemporary is dreadful, and their condition is a scandal and reproach to the community at large. We call attention to it in the earnest hope that something may be done by the Government towards the mitigation of the sufferings of those who are the victims of this terrible scourge, and that means may be found for establishing asylums where they could be kept apart from the healthy community. The lepers in the Dhurrumsala have no furniture, not even cooking utensils. Every day two pounds of rice and three pice are given to each. Only those who are very much afflicted indeed can be taken into the refuge; those who are not so bad are told to go away—that is, they are in effect told to go and beg, until they become bad enough to be admitted. Within the Dhurrumsala there are men and women—and children. The latter are the offspring of the adults; they do not, as a rule, show signs of the disease till they are about fifteen, but it generally lays hold of them sooner or later. Children are born to leper parents in the Dhurrumsala; no separation of the sexes is enforced or even thought of. Yet one would counsel an inexorable separation in mercy to future generations. Men and women with their limbs wasted till only the outline of the bones remain, or else swollen out of all form of limbs, sit or lie on either hand. And for none is there either medical care or medical comforts. The two pounds of rice and the three pice for fuel to boil it, constitute their only resource. "No relative ever visits them or sends them food or money; they are cut off from their families and from the community of their native villages; no priest of any faith, no doctor—save one, whose name we are told not to publish—no man or woman goes amongst them to give material or moral consolation of any kind. They are abandoned of God and man, and were it not that the Dhurrumsala gives them the half of a six-feet cell in which to lie, and a handful of rice with which to sustain life, they would die in their sores along our streets and in our compounds."

FEEDING BY SUBCUTANEOUS INJECTIONS.

A method of forcible alimentation, which possesses at least the merit of novelty, has recently been put in practice by Dr. J. Krueg, who narrates his experience in the *Wiener Med. Wochenschrift*. It consists in the injection of aliments into the subcutaneous tissue by means of a hypodermic syringe. Dr. Krueg recalls the fact that it has been shown by MM. Menzel and Pereo that nutritious matter may be absorbed in this way; a quantity of fatty liquid, from one to eight drachms, having been taken up in forty hours, and that solutions of sugar, milk, and yelk of egg act in the same way. Peptones have also been shown to be thus absorbed by Stricker and Oser. Dr. Krueg tried the method in a case of insanity with refusal of food, in which, the patient having been nourished for twenty-seven months by means of the stomach-pump, and the introduction of the tube becoming difficult from his violence, at one time it could only be introduced once in ten days. Dr. Krueg, therefore, injected about half an ounce and then one ounce of oil daily beneath the skin, dividing this quantity between from two to five different points of injection, the operation being done gradually, and lasting about an hour. The injection was not painful, and the swelling disappeared by the next day. Beaten-up egg was not so successful, producing an abscess. For nine days at a time the patient was entirely dependent on this process for nourishment, which was subsequently repeated several times. We need scarcely say that this method of feeding is one not likely to be of much use; and, indeed, it seems to have been required in this case only because the old and barbarous method of feeding by the stomach-pump was employed, instead of the more simple and expeditious way of feeding by the nose. As a means of inducing unwilling patients to take food, the punctures required may have as much value as any other mode of torture; and, indeed, some temporary result of the kind seems to have been gained in the case narrated.

THE PRESS AND FALSE DEGREES.

After the trouble which has been taken by the authorities of the United States to expose the system of selling medical and other degrees, it is lamentable to see respectable papers doing their best to give a fresh lease to this system of fraud, by giving regular titles to persons holding these worthless certificates. A case in point is now under our notice. *The Redruth Times and Camborne Advertiser* gives a report of a very useless coroner's inquiry into the cause of death of Mary Ann Angove, the inquiry leaving the cause of death as much a mystery as it was before. The only facts elicited were, that the deceased was subject to giddiness, and shortly before her death had a draught from one "Dr." Rowe, as our contemporary calls the chemist who gave this draught, containing, as he admitted, chloral and camphor and opium. This gentleman seems to have had that convenient amount of self-respect which allows a man to buy the M.A. and Ph.D. of Philadelphia, U.S., an institution which we officially know to have "no legal or actual existence," having been deprived of its charter "on account of its notorious and shameless sale of degrees and similar rascalities." The words we quote are the words of the Acting Commissioner of the Bureau of Education, Washington. Surely our press should not perpetuate and abet the use of titles so disgraceful. The way in which, in common newspaper reporting, the reporter confers degrees indiscriminately on all medical men may be leniently regarded as a piece of carelessness, but it is a very different matter when a chemist dealing out deadly medicines on the strength of high sounding but highly discreditable titles, is styled "Dr." Rowe, without the commas, as if he were a duly registered practitioner in possession of a respectable degree. Our contemporaries can really help the American authorities, and all who represent respectable colleges, by using medical titles only in cases in which they are real and registerable, points easily to be ascertained.

CHOLERA RISKS IN INDIA.

The *World*, in adverting to the fact that the prevalence of cholera in the Annamully Hills will prevent the Prince of Wales from entering one of the finest fields for sport in India—the Annamullies being the favoured haunts of the largest elephants in India,—indulges in a computation as to the mortality of cholera, about which all we can say is that we heartily wish it were true. Our contemporary says that it is computed that one European of pure blood dies of cholera in India out of thirty-seven attacked, and that one such European is attacked to 74,000 of the natives of the country. Without claiming any special means of judging of the accuracy of these statistics, the statements, nevertheless, appear to our contemporary credible, and it proceeds to indulge in some pleasant calculations on its own account. What are the facts? The proportion of fatal cases to attacks assigned in different epidemics have varied; but the mortality from cholera in all countries is very great. The period of the epidemic influences the mortality; for, at the first onset, the larger number of those attacked die, then the mortality descends to one-half, until, at the end of the epidemic, a large proportion recover. The uniformity of this law in different cholera epidemics in different countries is very remarkable. We may state roughly that of the European troops serving in India, about one-half of those attacked with cholera perish. As is well known, officers are much less liable to contract the disease than private soldiers; but, when attacked, no great difference is observed in the mortality. The relative liability of Europeans in India to cholera as compared with the natives of that country we need not now discuss.

SCIENTIFIC OPINIONS USED AS ADVERTISEMENTS.

THE letter of "A Provincial Physician," which we print elsewhere, illustrates the danger which besets the giving of a written opinion on any article of trade. The writer, understanding that a certain prepared food was not advertised, expressed in a letter his good opinion of it. Within a week the letter was printed and circulated among the professional men of the district, to the great annoyance of our correspondent. This kind of annoyance is a very common one. Few professional men of repute would wish to see their names attached to a trade puff, and yet, if they have given a written opinion without any stipulation expressed or implied, it is difficult to see how they can help themselves. For professed analytical chemists the difficulty is of course greater than for medical men, for it is their duty to analyse and report upon every article sent to them, and very frequently they do not know the object of their client in having the analysis made. The report, once delivered, becomes the property of the client, who, in the absence of an express stipulation, is entitled to use it as he likes. The only safe course for those professional men who object to seeing their names on every hoarding in the country in connexion with nostrums and foods, is to insert in the report a stipulation that it shall not be used as an advertisement.

THE POLLUTED RIVER BASINS OF GREAT BRITAIN.

THE Sixth Report of the Rivers' Pollution Commission contains an interesting and elaborate map showing the entire area of the polluted river basins of Great Britain. The sources of pollution are severally from sewage, fibre (which includes cotton and woollen manufactures, calico and silk printing, dyeing and bleaching, and paper manufactures), chemical manufactures (including alkali works and mines), metalliferous and salt mines, collieries where coal is washed, works of China clay and metal trades, of brass founders, iron and steel wire drawers, galvanisers, file, saw, and edge tool manufactures, cutlers' grinders, and tin-plate workers. Special pollutions also include alcohol distilleries, paraffin oil, starch, and sugar refining works, and tan works. The counties that appear by this map to give least pollutions as to their river basins are Kent, Sussex, Dorset, Wilts, North Devon, Pembroke, Cardigan, Carmarthen, East Lincolnshire, and East Yorkshire. The North-west parts of Scotland are also tolerably free.

ENTERIC FEVER ON BOARD THE "CORNWALL" SCHOOL-SHIP.

THE epidemic on board this ship is not yet entirely at an end. Four doubtful cases occurred at the beginning of this week, and were removed to the shore hospital. A total of 43 cases are now under treatment—namely, 12 at the Seamen's Hospital, 4 at St. Bartholomew's, 23 in the Corporation's hospital-ship *Rhin*, and 4 at Purfleet. A detailed report of the rise, progress, and causes of the epidemic has been sent from Guildhall to the Local Government Board by the Port Sanitary Committee of the Corporation. For although the drinking water was undoubtedly polluted between the shore and the ship, on account of the faulty mode of conveyance, further examination has shown that the water, as delivered at Purfleet by the Grays Company, bears distinct signs of sewage contamination. This company supplies several villages in Essex, as well as a large number of isolated houses, before Purfleet and the *Cornwall* wharf are reached, so that it appears very important, in order to prevent further mischief, that the precise spot at which the pollution occurs should be accurately ascertained. We are informed that the main is more than twelve miles in length, with various branches, so that the inquiry will necessitate a great deal of care and labour, and one well worthy the attention of the Medical Department of the Local Government Board. Meanwhile the *Cornwall* authorities, hampered as to funds and the somewhat "intermittent" control of the Home Office, have but partially carried out the recommendations of the port medical officer of health. There are, in fact, several predisposing as well as exciting causes to account for the outbreak.

THE LYMINGTON GUARDIANS AND RETIRING ALLOWANCES.

IN July last Mr. Nicholas Adams resigned his appointment as medical officer under the Lymington Union, after a service of forty-seven years. As to the character of this service we have the direct testimony of the guardians that the duties had been discharged in a most exemplary manner, and "most undoubtedly to their entire satisfaction." In due time Mr. Adams very naturally applied for a retiring allowance. It will scarcely be credited that the guardians have refused it. Length and faithfulness of service are thrown away upon some employers, amongst whom we fear we must reckon the Lymington guardians. These gentlemen seem to us to be acting at least ungenerously in this matter. They are unwilling to establish the precedent of superannuating their officers. We give them full credit for this unwillingness. But the law contemplates such a course, and they refuse to take it. It is true that the law leaves the gift in the discretionary power of the guardians, and in this fact they may find an escape from the charge of breaking the letter of the law. But they not less glaringly violate its spirit and intention in a case where most men, and we will venture to say most boards of guardians, would have been eager to do all that the law permitted to testify respect for an officer. The Board has refused a second time to superannuate Mr. Adams. We hope for its own credit's sake that it will even yet reconsider its decision.

THE PRINCE OF WALES.

As we ventured to state, the projected tour of the Prince of Wales in India would be a purely provisional one, subject to any alterations that might be rendered necessary by the state of health of the inhabitants of any given district which the Prince might have to traverse. By the latest telegrams, it would appear that His Royal Highness's visit to Madras has been abandoned on account of the prevalence of cholera in that presidency. The telegrams that have reached this country have already informed us as to the health and doings of the Prince up to very recent dates, and anticipated news that would come by letters. We are glad to learn, however, that the health of His Royal Highness during the passage to India continued excellent, even in the hottest part of the Red Sea, and when the ship was in a calm. Notwithstanding that the air in the cabins was 83° to 84° F., and laden with moisture, and the seawater was as hot, or nearly so, as the air, all on board the *Serapis* were in good health, the Prince apparently the strongest of the party, and thoroughly enjoying the voyage. As soon as the *Serapis* began to meet the southerly wind, which blew strongly through the Straits of Babul Mandel, the thermometer commenced to fall, and from having reached as high as 86° in the cabins, with 6 to 7 degrees of evaporation, it fell to 79° and 80° F., and became lower still on passing the Straits.

BORACIC ACID IN THE TREATMENT OF RINGWORM.

Surgeon-Major Watson reports in the *Indian Medical Gazette* that he has lately employed boracic acid with very great success as an external application in the treatment of the dermatophyta or vegetable parasitic diseases of the skin. He was induced to try this remedy from witnessing its employment as an antiseptic in the Edinburgh Infirmary wards. The diseases in which he has hitherto used boracic acid have been the different forms of tinea (T. tonsurans and circinata), and in that very troublesome form of the disease which affects the scrotum and inner side of the upper part of the thighs of many Europeans in India. Dr. Watson declares that the external application of a solution of boracic acid acts like a charm in such cases. An aqueous solution of boracic acid of a drachm to the ounce, or as much as the water will take up at ordinary temperatures, is employed. The affected parts should be well bathed with the solution twice daily, some little friction being used, and it should not be wiped off, but allowed to dry on the part. The remedy is said to be so simple, cheap, and efficacious, that it has only to be once used to be preferred to all other remedies of the same class.

ARTIFICIAL SKATING.

The rapid multiplication of skating rinks is a proof that artificial skating meets a real want and makes a useful addition to our modes of exercise and recreation. After some personal experience of it we desire to record our high sense of its value. There are in our climate a large number of cold and dull days in the course of the year, in which skating on ice is not practicable and yet skating on wheels is most enjoyable. It is as good for girls as it is for young men. If they do not learn quite so quickly, they make up by greater ultimate proficiency and grace. Without denying that a little of the attractiveness of the rink is due to opportunities it affords of a little quiet flirtation, it deserves support as a means of exercise and a stimulus to active locomotion. The care to maintain perpendicularity is wonderfully expulsive of other cares. Of course there is a risk in it, as there is in every game worth playing at; but with care and a little more provision for good teaching, the risk is very slight for any persons adapted to the exercise. One point is very important—that the rink should be open. In other words, the skating should be in the fresh air. With this qualification we hail artificial skating as a most brilliant and useful addition to our forms of exercise, and the means by which the sensations of youth are conserved.

EDINBURGH UNIVERSITY CLUB.

The quarterly dinner of this Club was held on Wednesday evening, the 10th inst, at the St. James's Hall Restaurant. Sir William Fergusson, Bart., LL.D., occupied the chair, and about forty members and guests were present. Several new members were elected, and some new names were proposed for election. The usual toasts were given from the chair, and that for "The Visitors" was replied to by Lord Theobald Butler.

The annual general meeting will be held in February next, before the quarterly dinner; and it is hoped that the President of the Club, H.R.H. the Duke of Edinburgh, may occupy the chair at the dinner in May.

SCARLET FEVER IN LONDON.

During the last month sixty-three persons suffering from scarlet fever were admitted into the London Fever Hospital, and at the present time the number of applications for private rooms exceeds the accommodation provided in that institution. A few patients have been admitted into the general ward, while waiting until private rooms become vacant. The necessity of the isolation of fever patients is becoming so fully recognised by the public, that the private rooms in the London Fever Hospital are sure to be freely used during the present epidemic.

THE CONJOINT SCHEME.

Dr. Acland and Dr. Rolleston have been appointed to represent the University of Oxford at the conference of examining bodies to take again into consideration the formation of a Conjoint Board for England, and Dr. Philipson and Dr. G. Y. Heath have been delegated by the University of Durham to represent that body at the conference. There has been as yet no meeting of the conference.

EPSOM COLLEGE.

The Report of our Sanitary Commission on Epsom College will appear next week. In the mean time it will be satisfactory to the parents of the boys there to state that no fresh cases of scarlet fever have made their appearance. Of the five boys originally attacked, four are convalescent, whilst one is still suffering from the sequelæ of the disease.

Those of our readers who are interested in the study of comparative pathology and epizootics—studies which are growing in importance in connexion with epidemiology and what may be termed medical philosophy—will find much valuable information from time to time in the *Veterinary Journal*, a new publication, conducted under the auspices of Mr. George Fleming, of the Royal Engineers, whose scientific and literary labours in connexion with comparative pathology and other subjects of an allied character are well known. The numbers of the *Veterinary Journal* that have come under our notice have contained several excellent articles, some of which have possessed considerable interest for those outside the circle of veterinary surgeons.

Scarlatina appears to be very prevalent in the military, as well as the civil population at the present time. Owing to an outbreak of that disease at Colchester Camp it was, quite recently, not deemed prudent to allow the drafts of the 18th and 96th Regiments, under orders for India, to embark in one of H.M.'s troopships, and they were detained accordingly. At Aldershot, also, we learn that the disease is prevalent in one of the camps, and that some of the schools there have been temporarily closed in consequence; and cases of the same disease have made their appearance at other camps and garrisons.

According to the latest information, the cholera had diminished in Madras and Mysore, although at Madras itself it had somewhat increased. The disease has been confined to the native races. In the Bengal Presidency the disease was still prevailing in various districts to a certain, though slight, extent, and notably at Lucknow, Delhi, Allahabad, Morar, Meerut, Umballa, and a few other places.

We understand that Mr. Jonathan Hutchinson has accepted the invitation of the Council of the Pathological Society to open a discussion on Syphilis, to take place in January next.

We gather from a paper read before the New York Medical Society by Dr. Fordyce Baker, whose name is familiar enough in this country, that the surgical wards of the Bellevue Hospital in New York were recently thoroughly disinfected by chlorine gas and ozone, the process of purification being conducted on a most extensive scale. For generating the chlorine five thousand pounds of the black oxide of manganese, twenty-five sacks of salt, and one hundred and sixty pounds of sulphuric acid were used, while the requisite amount of ozone was obtained by the employment of one hundred pounds of manganate of soda and the same quantity of sulphate of magnesia. The result of this cleansing was markedly beneficial. The fatality from septic diseases had previously been alarmingly great in the wards, while but one case of pyæmia, and that a very doubtful one, has occurred since the disinfection of what Dr. Fordyce Barker calls "nosocomial malaria."

In London last week 1449 deaths were registered, including 1 from small-pox, 43 from measles, 116 from scarlet fever, 12 from diphtheria, 49 from whooping-cough, 20 from different forms of fever, and 24 from diarrhœa. Scarlet fever was especially fatal in Hammersmith, Islington, Bethnal-green, Bermondsey, Battersea, Peckham, and Deptford. The deaths referred to diseases of the respiratory organs amounted to 349, which number, although greatly in excess of the mortality of the preceding weeks, was below the corrected average. It is interesting to learn at this time that the latest returns from Indian cities give the following death-rates :—Bombay, 25 ; Calcutta, 35 ; and Madras, 38. In the latter city 62 deaths occurred in one week from cholera.

Our contemporary, the *Indian Medical Gazette*, lately informed its readers that quite a panic had taken place in Calcutta in consequence of the supposed existence of parasites in the commonly eaten and favourite water fish. The sale of this fish was prohibited, and the health officer of Calcutta was ordered to make a special inquiry into the matter. It was found that the fish was wholesome enough, and that what had been mistaken for lumbricoid worms were spinal nerves ! In one instance a piece of nerve had been sent to an expert for the purpose of having the identity of the parasite determined. The fish fed in the dirty Ganges is not, we suppose, very delicate.

The encouraging results that have followed the method of treatment of leprosy by gurjun oil, which we have more than once noticed, seem to be attracting attention. We learn from the *Madras Mail* that a piece of ground has been given by the Directors of the Monegar Choultry to the superintendent of a lazaretto on the recommendation of the Deputy Inspector-General of Hospitals, who intends erecting sheds for patients to enable him to experiment with the gurjun oil on a large scale.

We understand that a circular has been issued to certifying surgeons under the Factory and Workshops Acts, requesting a statement of the amount of pay received by them within the last twelve months in the discharge of their duties. The information is for the use of the Royal Commissioners on the Acts. There is an intention to make these Acts more comprehensive in their scope.

More than one of the smaller towns in Devonshire have recently suffered from severe epidemics of scarlet fever or typhoid fever, or both ; and in every instance they have been clearly traced to sanitary apathy and the grossest disregard of the necessity for pure air and water to the health of man.

The want of a hospital for the reception of patients with infectious disease in Stockport has been felt for some time. Small-pox has been more or less prevalent in the town since the autumn of 1874, but hitherto little attempt has been made to isolate cases of the disease. The neglect of th authorities has at last roused the attention of the Local Government Board, and they have addressed a letter to the guardians urging them to provide the required accommodation. The guardians have referred the matter to the Town Council, who in all probability will pass it back again to the Local Government Board.

Some very severe and peculiar cases of pneumonia continue to occur among the native Indian regiments forming our Punjab frontier force. It has rather puzzled a few of the medical officers who happened to treat the disease, and is compared to the pleuro-pneumonia of cattle in this country. Comparative experiments are being made to prove the communicability of pneumonic disease, and few will doubt that this is a direction in which work might be prosecuted with the most hopeful chance of good results.

We have already reported a severe outbreak of enteric fever in Crediton, a small town with a population at present estimated at about 4300. The memorial of the inhabitants may be taken as a protest against a long course of inaction on the part of the urban sanitary authority of Crediton, whose estimate of the value of public health is exceedingly low, if we may judge from the fact that they have fixed the salary of their medical officer of health at £7 per annum !

The weather on Sunday last, the day appointed for the collection on behalf of the Dublin Hospital Fund, was most unpropitious, there being all the morning a constant downpour of rain ; and, as an extreme instance of the severity of the weather, it may be stated that the clergyman who preached in Clontarf Church on that day was obliged to reach the building by means of a boat.

On the 20th (this day) the election by the Fellows of the Royal College of Surgeons in Ireland will take place of a Vice-President of the institution, in the room of the late Mr. John Hamilton. Dr. George H. Kidd, late member of the Council, and obstetric surgeon to the Coombe Lying-in Hospital, is a candidate, and it is considered probable that he will be elected without opposition.

The adjourned inquiry into the circumstances connected with the death of Mary Jane Bell was held last Wednesday before Dr. Hardwicke, when the jury returned a verdict, "That the deceased, Mary Jane Bell, had died of tubercular disease and disease of the kidneys, accelerated by her removal from King's College Hospital by her friends."

Two ships, from the East Indies and South America respectively, have arrived in the Thames with cases of scurvy on board. Five men were landed from the former ship at Queenstown, and five also from the latter at Falmouth. The Board of Trade have directed official inquiries to be made as to the cause of the outbreaks.

Surgeon John Neesom Stone, R.N., has been specially promoted to the rank of staff-surgeon for services in the recent expedition against pirates up the river Congo. He was the senior medical officer in charge of the force landed.

Professor Hebra has lately been failing in health. He has been granted leave to appoint a substitute for this winter's lectures, and will take this opportunity of recruiting his strength.

We would this week call the attention of our readers to the Ranald Martin Memorial Fund, which will soon be closed. Further subscriptions will be received by Mr. Pollock, 36, Grosvenor-street; Mr. O'Brien, 35, Lancaster-road, Westbourne-park; and Messrs. Herries, Farquhar, and Co., 16, St. James's-street.

Dr. Frankland, F.R.S., reports that the Thames waters supplied last month by the Grand Junction, Southwark, and Lambeth Companies were slightly turbid, those of the two last named containing "fungoid growths." The Kent Company's deep well water was found to be of excellent quality.

The City Commission of Sewers have determined to expend a sum of over £58,000 in the improvement of a most unhealthy district on the southern side of Ludgate-hill, under the provisions of the Artisans' Dwellings Act. The scheme was unsuccessfully opposed by the Ecclesiastical Commissioners.

Mr. W. E. Gladstone has been unanimously elected a member of the Board of Trustees of the Hunterian Collection of the Royal College of Surgeons, in the vacancy occasioned by the death of Sir Charles Lyell.

Seven surgeons in the Royal Navy have been recently promoted to the rank of staff-surgeons in vacancies caused by death or retirement in the higher ranks of the service.

OPHTHALMIA IN THE METROPOLITAN PAUPER SCHOOLS.

During the month of December, 1873, a comprehensive paper on this subject from the pen of Mr. Brudenell Carter was published in The Lancet. This paper was read at a Conference of Chairmen and Vice-Chairmen of Boards of Guardians, and we may assume that in consequence of the interest thereby created, as well as the intrinsic importance of the subject, an official examination of all the metropolitan pauper schools was ordered by the Local Government Board in the autumn of last year. This examination was performed by Mr. Edward Nettleship, and his report, now before us, is by far the most exhaustive and painstaking piece of work on this subject that has as yet been published.

The inspection was made within six weeks, and included seventeen schools that accommodated collectively at the time 8798 children, including 119 then at the Margate Infirmary. Of the total number, 12 per cent. had at the time of inspection more or less conjunctival discharge, about 30 per cent. had granular lids of considerable severity (although without any discharge or other discomfort), and it was calculated that 15 per cent. (i.e., 12 per cent. with discharge, and 3 per cent. with other symptoms) were suffering from active ophthalmia requiring isolation and more or less active treatment. A total of 579 children, or about 6·5 per cent., were in the infirmaries at the time of the visits, so that 8 or 9 per cent. were still at large in the body of the schools. The number of children with healthy eyelids throughout the schools was equal to 15 per cent. of the whole number, and 35 per cent. of the children were found whose eyelids were in a condition of slight disease, "or were in general terms predisposed to obstinate and relapsing ophthalmia." A total of 793, or 9 per cent., were found with ophthalmic corneal damages, both eyes being affected in 353, and one cornea only in 440 cases. As regards the permanence of these opacities, no accurate classification could be made. The author places them in six divisions, which comprise 44 children with one or both eyes lost, 66 severe damages, 229 moderate damages, 358 slight damages, 78 very slight damages, and 21 with no damage—i.e., eyes with opacities and irregularities which from their position could not interfere at all with sight. The total number of non-ophthalmic corneal damages from all other causes was 59, or ·66 per cent. of all the children.

In a general review of the subject, we may omit special mention of the ophthalmic state of the schools separately, to which Mr. Nettleship gives an elaborate chapter of statistics; nor is it necessary to specify the worst or the best schools, for, as the author remarks, it is difficult to say which school is worst as to ophthalmia, if we include past and present conditions. In passing on to notice the relation between the ophthalmic state and life in these schools, the author, in remarking upon the value of ascertaining the ophthalmic state of a large number of poor children living at home in London and in various parts of the country, records that the only contributions on this head are found in the London Orphan Asylum at Watford, where in 1873 nearly 50 per cent. of the children had well-marked sago-grain eyelids (although no ophthalmia had existed in the institution); in the examination of 256 national school children in a small town and village in Oxfordshire, where the same predisposing conditions existed in at least 35 per cent.; and in a third group of 86 children in two workhouse schools in the same county, in which sago-grain eyelids were found to the extent of 50 per cent. of all the children. The conclusions drawn from the statistics above quoted are, however—(1) that the number of bad granular lids varies directly as the length of time during which the children have lived in these schools; (2) that the number of ophthalmic corneal damages varies directly in the same way; (3) that the number of ophthalmic corneal damages varies directly as the number of badly granular lids. The actual state of the children under one month and one year in the schools respectively shows that "the risk of getting ophthalmia is very far greater in the metropolitan pauper schools than outside them."

In considering the relations between ophthalmia in these schools and the age and sex of the children forming them, it is recorded that children below seven or eight years of age are practically far more dangerous as sources of contagion than boys or girls. Corneal damages are most abundant and most severe in the girls; discharge from the eyes is commonest and most profuse among the infants, and next among the boys; and the boys are much less, and the infants somewhat less, liable to lose their sight by violent ophthalmia than the girls. In discussing the influence which conditions independent of school life have on the ophthalmic state of the children in these schools, it is reported that the London children are, practically speaking, worse than the country children; and hence that predisposition to the disease bears a somewhat direct proportion to density of population; that Irish children are more liable to ophthalmia than English children; and that, as a rule, the eyelids are worse in orphan and deserted children than in those with parents.

The last and, practically speaking, the most important section of the inquiry related to the possibility of getting rid of ophthalmia without abolishing the schools. Mr. Nettleship very justly says: "It is impossible to form a precise estimate of the extent to which the disease, as it occurs in the metropolitan schools, injures the prospects of those who suffer from it." No less than 55 per cent. of all the children in the schools have had at least one attack of eye-disease requiring treatment, and relapses are the rule rather than the exception. Separate probation wards and quarantine establishments have been suggested, the latter being, in the opinion of the author, by far the better plan. But every child should be kept in that so-called quarantine for atleast a fortnight after leaving the workhouse before being allowed to join the body of the school, and some want a much longer time. The management of ophthalmic cases actually in the schools need not be discussed, because we write for the future rather than the present aspect of things. But the points that require alteration refer categorically to—(1) general overcrowding; (2) bad ventilation; (3) deficient and defective provisions for exercise in the open air; (4) defects in the infants' schools and junior boys' schools; (5) want of cleanliness; (6) food; and (7) size of schools. All these defects do not exist at all the institutions under consideration; for example, in the *Goliath*, off Grays, though the cubic space is small, the ventilation is particularly good. But increased artificial warmth in the buildings, grass fields for exercise, and a larger staff of officers are required, particularly as regards the infants and forward boys. "The commonest means of contagion are the children's fingers, not used purposely, but rubbed, accidentally or in play, over the child's own face and eyes, or over those of its companions." As to preventive measures, an abundant supply of clean water and towels is of course essential, and a great many valuable remarks are offered as to the manner and "stuff" of the clothing adopted in these schools.

The report concludes with some observations on the size of these schools, which are noteworthy. Mr. Nettleship remarks, in effect, that though there is no positive evidence as to the sanitary disadvantages of a large as compared with a small institution, the common sense view of the question is very much in favour of the latter. Small numbers are of course more manageable, but very much of success hinges on the capacity of the superintendent.

We have of course omitted much in the way of detail that is both useful and interesting, and must refer our readers to the report, the able character of which has seldom been excelled.

Correspondence.

"Audi alteram partem."

MEDICAL EDUCATION.

To the Editor of THE LANCET.

SIR,—In your report of the meeting of the Council of the Royal College of Surgeons, I observed a suggestion by Mr. Marshall of a compulsory examination at the end of the student's first winter session, or immediately after the commencement of the succeeding summer session. I trust that the expression of an adverse opinion will not be considered by the Council an act of presumption on my part, but I cannot think that the multiplication of examinations can prove beneficial. What with frequent *vivâ voce* and occasional written class examinations, prize examinations, and, at some schools, even *test* examinations, it would appear that our students are already over-examined. It is true that the examination proposed would be more authoritative, but we are not told what would be the result in the case of those who failed to pass it, or how long in such an instance the Primary Examination proper would be postponed.

The blot in our present system, now that so much is required of our students, seems to be that men are allowed, and even required, to attend hospital practice and lectures on the practical subjects while they are working in the dissecting-room and physiological laboratory. Students who seek the degrees of the University of London, or who intend to remain at a medical school four years, are careful to avoid this overlapping of subjects, but still they are obliged to put in an appearance in the wards to comply with the College requirements. On the other hand, the majority of students adopt the plan of crushing through all their hospital practice and lectures in two years and a half, or at most in three years, and present themselves badly prepared for all their examinations. See what this means in one of these student's second winter session. If he be industrious, he endeavours to attend lectures on anatomy and physiology, to work in the dissecting-room and physiological laboratory, to read up for his Primary Examination, and perhaps for a prize or two in his own school. One would think that this was sufficient for an ordinary brain to inwardly digest; but no, he is not content. He further vainly tries to profit by attending lectures on medicine and surgery, and by an *assiduous* attendance in the medical and surgical wards, on clinical lectures, and at post-mortem examinations and demonstrations; and I have even heard of a man taking a dressership. Can it be wondered at that a student should be somewhat bewildered on presenting himself for the Primary Examination?

In my humble opinion, and I have already given expression to it, the remedy is—to separate entirely the curriculum for the *Primary* Examination from that for the *Pass* Examination, the latter to be commenced after the Primary Examination has been passed. I am aware that reasons are given for maintaining the present system, but I am quite sure that the objections to it far outweigh these reasons. The knowledge of anatomy and physiology can be kept alive by testing it in its practical bearing upon medicine and surgery at the Pass Examination, and the result would be more satisfactory than at present if an uninterrupted study of those subjects had been previously secured. I believe that if our examining bodies enforced such a change as I have suggested, the "number of rejections" would rapidly diminish, and that "many would be diverted from" what is now too often an "idle and profitless course of study."

I have the honour to be, Sir, your obedient servant,

GEORGE COWELL.

George-street, Hanover-square, Nov. 13th, 1875.

ECCHYMOSIS OF THE SCROTUM.

To the Editor of THE LANCET.

SIR,—*Apropos* of Mr. Savory's lecture on this subject, I have at present a case of injury to the abdomen and scrotum under treatment, which is resulting so favourably that I think an account of the means employed may interest your readers.

A young man, aged nineteen, a miner, was engaged at his work in the coal-pit, when a large mass of stone from the roof fell upon him, inflicting severe injury upon the lower part of the abdomen and scrotum. I saw him shortly after the accident, when he was suffering from shock, the entire surface pale and cold, the scrotum somewhat swollen and slightly discoloured. He complained of severe pain in the right iliac fossa. He was ordered hot brandy-and-water, with hop fomentations to the parts injured. The following day general peritonitis had set in, and the scrotum was swollen to the size of a large cocoanut, blue-black in colour, and very tense. He was now ordered a dozen leeches to the abdomen, with calomel and opium internally. The scrotum was supported upon a folded napkin pinned round the hips, and swathed in a bandage saturated with a warm lotion composed of one ounce of tincture of arnica and one ounce of ammonium chloride to a pint of water. In two days the peritonitis had subsided. The lotion to the scrotum was continued, and with such good effect that to-day (the tenth since the accident) its appearance is perfectly normal, soft, and corrugated, without a trace of the residual fibrinous hardness so frequently seen in these cases.

I am, Sir, yours truly,

ALFRED GINDERS, M.D.

Normanton, November 16th, 1875.

SCIENTIFIC OPINIONS USED AS ADVERTISEMENTS.

To the Editor of THE LANCET.

SIR,—A few weeks ago I received through the post a specimen of prepared food from a chemist at some distance, with a letter asking my opinion of it, giving the composition of the food, and stating that it was not advertised. I made a careful trial of the preparation, and found it satisfactory, and wrote a letter in reply to the one I had received stating my good opinion of the food. I was induced to do this contrary to my usual custom, because the food was not advertised. Within a week it accidentally came to my knowledge that my letter was printed and circulated among my professional brethren in the district. I at once took steps to stop this unauthorised use of my letter, and obtained a promise that it should be forthwith discontinued.

I send you this little history in order that others may be warned by my unlucky experience, and may avoid, under any circumstances, giving favourable written opinions of drugs or foods, even to proprietors who do not advertise. May I also ask why it is that the names of distinguished members of the profession are still paraded in our newspapers, by means of testimonials in favour of certain electrical apparatus, and light-brown and pale cod-liver oils, not to mention a score of other articles which the student of the advertising columns of our daily and weekly papers might easily mention?

I am, Sir, yours truly,

Nov. 6th, 1875. A PROVINCIAL PHYSICIAN.

Medical News.

Royal College of Surgeons of England. — At an ordinary meeting of the Council held on the 11th inst., Mr. John Birkett was elected a member of the Board of Examiners in Dental Surgery, in the vacancy occasioned by the resignation of Mr. Hancock.

At the same meeting the following Members were elected Fellows of the College:—

Briscoe, John, L.S.A., Broad-street, Oxford.
Burroughs, John Beames, L.S.A., Clifton, Bristol.
Flower, Thomas Bruges, L.M. Dub., Bath.

The following gentlemen, having passed the required examinations for the diploma, were duly admitted Members of the College at meetings of the Court of Examiners on Tuesday and Wednesday last:—

Allen, Richards G., Belper.
Amphlett, Edward, Leamington.
Angove, William T., L.S.A., Bessborough-gardens.
Aplin, Alfred, Exeter.
Archer, Robert K., L.S.A., Highgate.
Bacon, Alfred T., L.R.C.P. Ed., Leeds.
Bigger, Samuel F., Belfast.
Blake, Henry, L.S.A., Bedford.
Bower, Ernest D., Leeds.
Bowling, Charles J. L., Ramsgate.
Brock, Charles de Lisle, Guernsey.
Carrington, Robert E., Brixton.
Chant, Thomas, L.S.A., London-road, Lowestoft.
Dennis, Augustine, L.R.C.P. Ed., Burnham, Westgate, Norfolk.
Edwards, Frederick S., St. Peter's-park.
Evans, Thomas, L.S.A., Pwllheli.
Godfrey, Charles Walter, Romsey, Hants.
Harvey, Thomas P., L.R.C.P. Lond., Pyrland-road.
Harvey, Henry Frederick, L.S.A., Gower-street.
Heard, Charles G., L.S.A., Truro, Cornwall.
Hicks, Henry, L.R.C.P. Ed., Wakefield.
Hutchinson, Joseph, L.R.C.P. Ed., Luton, near Manchester.
Iles, Alfred R., Fairford.
Jacobs, Henry Ralph, Aberdare, South Wales.
Jenkins, Aneurin, L.R.C.P. Ed., Longlwes, S. Wales.
Johnson, William B., L.S.A., York-road.
Kellard, James T. W. S., L.S.A., Stoke Devonport.
Kidd, Walter Aubrey, Blackheath.
Leigh, Reginald H., L.S.A., Aberdare, South Wales.
Livy, Ferderick Y., Bolton.
Manden, Horace, L.S.A., Marlborough.
Mason, John W., M.B. Aberd., Grantham.
Morgan, Evan A., L.K.Q.C.P.I., Liverpool.
Morshead, Ernest G. A., Sidmouth.
Musgrave, Reginald V., L.S.A., Finchley-road.
Patmore, Tennyson D., Hastings.
Phibbs, Robert F., L.R.C.P. Ed., Boundary-road.
Pilkington, Henry, Liverpool.
Randle, James, L.R.C.P. Lond, Lizard, Cornwall.
Shain, William F., Liverpool.
Simon, Robert M., Nottingham.
Steil, George R., L.R.C.P., Shepherd's-bush.
Truman, Charles Edwin, Old Burlington-street.
Whitby, Edward V., Birmingham.
Wilkins, Gilbert H., L.S.A., Brixton.
Woodward, Frederick E., Coventry.

Apothecaries' Hall. — The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on Nov. 11th:—

Harper, Robert Russell, Oakden-street, Kennington-road.
Roth, Bernard Mathias Simon, Wimpole-street.
Thompson, Harry Young, Newport, Monmouthshire.

The following gentlemen passed the Primary Professional Examination on the same day:—

Arthur Alexander Blakiston, University College; Walter Strover and John Todd, Guy's Hospital; Charles Jerome Woollett, Charing-cross Hospital; William Clarke Whitfeld, Bristol Infirmary.

Mr. T. Kirsopp has obtained the Jeaffreson Exhibition of £20 per annum for two years at St. Bartholomew's Hospital and College.

Coroners' Inquests.—Last year there were held in England and Wales 27,184 inquests, the cost of which, including coroners' salaries and allowances, was £82,533 15*s.* 1*d.*

Mortuaries in the Metropolis.—The motion of Dr. Joseph Rogers for the appointment of a deputation to wait upon the President of the Local Government Board regarding the establishment of mortuaries in the metropolis, was carried at the Strand Board of Works last Wednesday.

The Court for the Consideration of Crown Cases Reserved on Saturday affirmed the conviction of John Robert Downes, one of the "Peculiar People," who at the Central Criminal Court was found guilty of manslaughter for having neglected to supply his child, two years old, with medicines and medical aid when it was sick, from the want of which the child died.

Mr. W. A. Ryder, a grocer in an extensive business at Bicester, was, at the Bicester Sessions, sentenced to seven days' imprisonment for refusing to have a child vaccinated, and declining to pay 20*s.* and 10*s.* costs. The defendant is known as a public speaker against vaccination.

The Stockport magistrates on Saturday imposed the full penalty of £5 on a woman who had sold some of the clothing of a son who was suffering from small-pox. The result of the defendant's indiscretion was that several other persons were attacked by the disease.

Last week the Alcester magistrates imposed a penalty of £5, and 19*s.* 6*d.* costs, upon a journeyman carpenter for exposing a child whilst suffering from scarlet fever. The child was sent to the Grammar School, Studley, whilst in the state of infection. Eight persons in the schoolmaster's household contracted the disease, and one of his children died from it. Great culpability on the part of the defendant was shown.

Testimonials.—A testimonial in the shape of an elaborately carved inkstand was lately presented to Mr. R. T. Warn, of Highgate-road, by the members of a club, as a token of the esteem in which he is held, and in appreciation of his services as medical officer.—Dr. Charles Fryer, on his removal from Openshaw to Sherburn, E.R., Yorks, has been presented with an elaborate timepiece bearing the following inscription:—"Presented to Dr. Fryer, by the members of Court Hero of the Baltic, 3528 A.O.F., for valuable services rendered as medical officer during the past four years. Sept. 18th, 1875."

Bequests, &c., to Medical Charities. — Mr. James Houghton bequeathed to the medical charities of Liverpool as follows:—To the Southern Hospital £5000, to the Royal Infirmary £500, to the Northern Dispensary £250, to the Southern Dispensary £250, and to the Medical Mission £100. The Doncaster Infirmary has received £3000 under the will of Mr. A. Barber. Mr. Peter Ormrod, of Halliwell Hall and Wyersdale-park, Lancashire, bequeathed £2000 to the Bolton Infirmary and Dispensary. The General Hospital, Nottingham, has received £200 under the will of Mr. John Gibson. The Drapers' Company have voted an additional donation of twenty guineas, and the Clothworkers' Company an annual subscription of ten guineas, in aid of the Royal National Hospital for Consumption, at Ventnor. An anonymous donor has given £500 to the funds of the Old Men's Asylum, Dublin.

Medical Appointments.

Brown, A., M.B., C.M., has been appointed a House-Surgeon to the Glasgow Western Infirmary, vice M'Calman, resigned.

Brown, J. L'Oste, L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer for the Sheriffhales District of the Shiffnall Union, Salop.

Cantlie, J., M.B., has been appointed Resident Surgical Officer to the Charing-cross Hospital.

Conolly, Mr. P. B., has been appointed Assistant Surgical Officer to the Charing-cross Hospital.

Cope, W. H., M.R.C.S.E., has been appointed Resident Medical Officer to the Leicester Amalgamated Friendly Societies' Medical Association.

Cotton, H., M.R.C.S.E., has been appointed House-Surgeon to the West Sussex, East Hants, and Chichester General Infirmary and Dispensary, vice Macpherson, resigned.

Cunningham, C. L., L.R.C.S.Ed., L.M., has been appointed Medical Officer and Public Vaccinator for the No. 3 District of the Hastings Union, vice Cumming, resigned.

Drysdale, Dr. A., has been appointed Certifying Factory Surgeon for Dunfermline, vice Douglas, resigned.

Dudley, W. L., M.D., F.R.C.S.E., has been appointed Physician to the City Dispensary.

Green, E. F. S., M.B., C.M., late House-Physician at the Western Infirmary, Glasgow, has been appointed Medical Officer and Public Vaccinator for the Bentham District of the Settle Union, vice E. Tatham, M.B., C.M., deceased.

Greenwood, J. W., M.R.C.S.E., L.M., has been appointed Medical Officer for the Hanley District of the Parish of Stoke-on-Trent, vice Burn, resigned.

Hamill, J. W., M.D., C.M., has been appointed Resident Surgeon to the Worksop General Dispensary and to the Cottage Hospital, vice R. A. Skinner, resigned.

Harrison, T. W., L.R.C.P.Ed., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Doneraile Dispensary District of the Mallow Union, Co. Cork, vice Reardon, resigned.

Hill, P. E., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Crickhowell District of the Crickhowell Union, vice Evan Parry, M.R.C.S.E., resigned.

Kendall, J., L.R.C.P.Ed., L.R.C.S.Ed., L.M., has been appointed Medical Officer and Public Vaccinator for the Conistone District of the Ulverstone Union, Lancashire, vice Bolton, resigned.

Loudon, J., M.D., has been appointed Medical Officer to the Police, Hamilton, Lanarkshire, vice Naismith, deceased.

M'Calman, D., M.B., C.M., late House-Surgeon, has been appointed a House-Physician to the Glasgow Western Infirmary, vice Green, resigned.

M'Kelvie, R. B., M.D., has been appointed Medical Officer to the Lorn Combination Poorhouse, and Parochial Medical Officer for the Parish of Kilmore and Kilbride, vice M'Gillivray, deceased.

Miller, T., M.B., C.M., has been appointed a House-Surgeon to the Glasgow Western Infirmary.

Moffatt, R., M.B., C.M., late Assistant-Surgeon, Hexham, has been appointed a House-Surgeon to the Glasgow Western Infirmary, vice M'Kellar, resigned.

Morris, H., M.B., F.R.C.S.E., L.R.C.P.L., has been appointed Surgeon to the Bloomsbury Dispensary, vice Cooper, deceased.

Murrell, W., L.R.C.P., M.R.C.S., has been appointed Demonstator of Physiology at University College, London.

Owen, Mr. W. G., has been appointed a House-Physician to the Glasgow Western Infirmary.

Parsons, H. F., M.D., M.R.C.S.E., has been appointed Medical Officer of Health for the Goole Urban Sanitary District, for one month, pending further arrangements.

Potts, Mr. L , has been appointed Assistant Medical Officer to the Charing-cross Hospital.

Protheroe, S. D., L.R.C.P., has been reappointed Medical Officer of Health to the Pembroke Urban and Milford Port Sanitary Districts.

Rigden, W., M.R.C.S.E., has been appointed a Surgeon to the Chelsea, Brompton, and Belgrave Dispensary, vice Whitmore, resigned.

Rodwell, E. M., L.S.A.L., has been appointed Resident Medical Officer to the Charing-cross Hospital.

Sewell, W. R., M.B., C.M., late House-Surgeon at the Glasgow Royal Infirmary, has been appointed a House-Physician to the Glasgow Western Infirmary, vice Wallace, resigned.

Sutherland, W., M.D., C.M., has been appointed an Hon. Physician to the Hartlepools Hospital, vice Reid, deceased.

Taylor, E., L.K.Q.C.P.I., L.M., L.R.C.S.I., has been appointed Assistant to the Resident Physician and Governor, State Criminal Asylum, Dundrum, Co. Dublin.

Turnour, H. E., M.D., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Tealby District of the Caistor Union, vice Read, resigned.

Walker, T. H., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer and Public Vaccinator for the High District of the Longtown Union, Cumberland, and Medical Officer of Health for the Longtown Rural Sanitary District, vice Hunter, appointed Medical Officer to the Teesdale Medical Union.

Woollett, C. E., M.R.C.S.E., has been appointed Resident Obstetrical Officer to the Charing-cross Hospital.

Births, Marriages, and Deaths.

BIRTHS.

Buzzard.—On the 9th inst., at Grosvenor-street, the wife of Thos. Buzzard, M.D., of a son.

Clarke.—On the 11th inst., at Coleraine-terrace, Salford, the wife of Alex. Carson Clarke, M.D., of a son.

Hewetson.—On the 7th inst., at Roscrea, the wife of M. J. Hewetson, L.R.C.S.Ed., of a daughter.

Ranger.—On the 7th inst., at Meadow Croft, Lower Sydenham, the wife of W. G. Ranger, M.R.C.S.E., of a daughter.

Scott.—On the 15th inst., at Marford, near Wrexham, the wife of R. R. Scott, L.K.Q.C.P.I., Surgeon-Major Army, of a daughter.

Stevens.—On the 16th inst., at Stoke Newington-road, the wife of Alfred Felix Stevens, M.B., of a son.

Stoker.—On the 9th inst., at York-street, Dublin, the wife of Wm. Stoker, F.R.C.S.I., of a son.

MARRIAGES.

Allt—Webb.—On the 10th inst., at St. Barnabas Church, Pimlico, Dr. Terence Thomas Allt, of Oaks House, Beckley, Sussex, to Catherine Elizabeth, eldest daughter of Dr. Edward Lowe Webb, of St. George's-road, Eccleston-square, S.W.

Archer—Bellis.—On the 3rd inst., at Jersey, E. G. Archer, M.R.C.S.E., to Harriette Constance, daughter of the Rev. R. Bellis.

Fry—Burrell.—On the 11th inst., at Frimley, Augustin B. Fry, M.R.C.S.E., to Emily Elizabeth, daughter of J. F. Burrell, Esq.

DEATHS.

Beaumont.—On the 12th ult., at Glenhurst, Toronto, Canada, Wm. R. Beaumont, M.D., F.R.C.S.E., aged 72.

Brett.—On the 16th inst., at Ladbroke-grove-road, North Kensington, John Brett, M.D., Deputy Surgeon-General (retired list) Madras Army, aged 57.

Fowler.—On the 30th of Sept., at Camberwell, Wm. Fowler, L.R.C.S.Ed., aged 39.

Griffith.—On the 8th inst., at Woodpark, Rathmines, Walter Griffith, F.R.C.S.E., of Guildford-street, Russell-square, aged 77.

Jameson.—On the 14th inst., at Sturry, Kent, Wm. Jameson, M.R.C.S.E., aged 78.

Lawless.—On the 1st inst., at Dublin, P. H. Lawless, Surgeon, aged 72.

Lees.—On the 10th inst., at Hodnet, Salop, B. Lees, L.S.A.L., aged 64.

O'Neill.—On the 10th inst., at Birkenhead, E. D. R. O'Neill, M.R.C.S.E., aged 40.

Palmer.—On the 12th inst., at Cheltenham, T. G. Palmer, L.D.S. R.C.S.E., aged 64.

Walker.—On the 7th inst., at Middleton House, Lee, Wm. Holmes Walker, M.R.C.S.E., aged 39.

Willson.—On the 6th inst., at Warwick-gardens, Kensington, G. Willson, M.R.C.S.E.

[N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*]

Notes, Short Comments, and Answers to Correspondents.

The Law about Life-saving.

We are glad it has at length been settled that the natural guardians of a child under fourteen years of age may not with impunity allow it to die for want of medical assistance, because they happen to entertain an opinion that "what is to be will be," and "Heaven alone can save." It is strange that any doubt should have lingered in the minds of lawyers after the passing of 32 Vict., cap. 122, s. 37—a statute enacted expressly to remove any uncertainty on the subject. It would be just as reasonable to leave the offence of starving a child to death, without a penalty, as to allow that of permitting him to die without the use of proper remedies, to go unpunished. If individual members of society are to do just what is right in their own eyes, and nothing more, the interests of the community cannot fail to be sacrificed. Helpless children are especially under the guardianship of the State, and its authority must be invoked for their protection whenever those who stand in the closest relations with them neglect or refuse to discharge their duty. The decision of the Court for Consideration of Crown Cases Reserved has happily destroyed the last vestige of an excuse for not putting the law in full force against those very Peculiar People, who, claiming the privilege accorded to fanatics outside the walls of a lunatic asylum, affect to "live by faith," and under that pretence leave those who are dependent on them for succour in sickness to die without the hope of relief by medicine. We trust there will no longer be any hesitancy in the practice of the Courts. What has always been an offence against humanity is now happily declared to be a crime in the eyes of the law. A rigorous administration is alone necessary to make the obligation which justice recognises extensively felt, and to ensure its being universally vindicated.

Mr. J. Griffiths (Treforgan, Cardigan) is thanked for his courtesy.

Size and Weight of English Children.

To the Editor of The Lancet.

Sir,—Will you allow me to appeal to the profession for assistance to complete a series of observations on the height, weight, and chest girth of our English race. I have already collected about 15,000 observations made on boys and men of all classes of society between the ages of 5 and 30 years. As my statistics vary considerably with the social position, occupation, &c., of the persons on whom the measurements were made, I have divided them into two series: one for the wealthier classes, whose physique has not been influenced by manual labour either of the children or their parents, and who have been well fed and nurtured; the other consists of the labouring classes and their children. Of the first series, which may be considered the standard of our race, I have collected about 6000 observations between the ages of 8 and 30 years from public and middle-class schools, universities, &c.; and of the second series I have obtained many thousands of observations between the ages of 6 and 30 years from primary schools in town, factory, and agricultural districts, from training ships, and from army and navy schools and recruiting depôts; also a number of measurements of infants at birth, supplied to me in reply to a former appeal to the profession through your columns. My standard series is incomplete from the period of birth to the age of eight years; and as children of this class are rarely sent to schools during this period, I must depend on a few observations from a large number of sources, and I shall be glad if I can induce some of the members of the profession to furnish me with the measurements and weights of some of their own children, or of others of the same social class who come immediately under their notice and care. My observations on the children of the labouring classes are incomplete between the ages of 1 and 5 years inclusive; but some of these may be obtained from infants' schools and from public institutions. As it is quite possible that many English statistics of this kind may have escaped my notice, I shall be glad to receive any references to them. I am, of course, aware of the existence of Belgium, German, Italian, and American statistics of a similar kind; but they are obviously of no use for my present purpose.

The exact information I require is the age last birthday, the sex, and the social status as distinguished above. The height is to be taken without shoes, the weight in ordinary in-door dress, including shoes, and the empty chest girth. This latter measurement should be taken with a tape passed round the nipples, and including the lower portion of the scapula, the arms hanging down by the sides. The child should be made to take a deep inspiration, and count ten in a loud voice before the measurement is determined. Children who are deformed, or suffering from any disease which would invalidate the measurements, should not be included; but none should be excluded for being merely under- or over-sized. My object is to get an average of the healthy population.

I am, Sir, yours &c.,

2, Bolton-row, May-fair, Nov. 9th, 1875. Charles Roberts, F.R.C.S.

Perkins' Metallic Tractors.

W. W. N.—Perkins was an American surgeon, practising in London. The "tractors" consisted, we believe, of small pieces of steel strongly magnetised, and were gently moved about on the surface of the skin of the affected part. To prove that the cures said to have been wrought by the tractors were due, principally at all events, to the exercise of imagination on the part of the patients, some persons had precisely similar instruments made of wood, painted and fashioned so as to resemble the original. These (the story goes) were publicly tried upon five hospital patients suffering, one from gout, and the others from rheumatism of one or more of the joints. All under this treatment are stated to have declared themselves much relieved!

Burns and Scalds.

Dr. Nitzsche, surgeon to several factories of Austria, stated at the Gräz Congress that he had noticed the workmen who met with burns obtaining much relief from the application of varnish. The latter forms a protective covering in the absence of epidermis, and granulation and cicatrisation are favoured. Dr. Nitzsche thought he could improve upon this, and tried to keep away Pasteur's germs by adding first carbolic acid, and subsequently salicylic acid, to the varnish. He considers that he thus succeeded in many cases in effecting prompt healing. These burns were probably in the third degree, with complete loss of epidermis. Another kind of burn where the epidermis is preserved, but much serum is secreted underneath, has fixed the attention of Dr. Marin, of Geneva. This physician grounds his treatment upon Dutrochet's law of exosmose, and thinks that the diminution of the serum effused under the epidermis should be obtained without the destruction of the latter. This is effected by the application of thick fruit jellies, say of quince, raspberries, &c. Compresses of lint should be soaked in the jelly, so as to become considerably thickened. The serum transudes into the compress, and when after a day or two it is removed, the epidermis is found shrivelled up, and the parts beneath protected from inflammation and ulceration. Dr. Marin insists upon the rule that when pieces of clothing are adherent to the burned surface, they should not be removed, for fear of dragging the epidermis with them. The compress should be placed on the clothing material, and the exosmosis will eventually go on just as well. Dr. Marin quotes, in a pamphlet on the subject, several cases well calculated to recommend this kind of treatment, concerning which he is very enthusiastic. It is well known that a long time ago jams and syrups were used in France, *empirically*, in cases of burns. Louis XIV. having met with a burn on his hand, his valet de chambre plunged it immediately into a jar of jam with much relief.

Police Courts and Medical Fees.

To the Editor of The Lancet.

Sir,—A feeling pervades the profession generally that while the remunerations for the services of a medical man are various and somewhat doubtful when taken in connexion with the general public, those fees which are legally claimable for services rendered to the State are definite and sure. Such an impression, no doubt true in the main, is not without its exceptions, which, if made only to prove the rule, are none the less obnoxious to those who may be the subject of this occasional irregularity. An instance fresh in my own experience prompts me to lay the brief particulars before you and my professional brethren.

On the 17th of August my attendance at the Marylebone Police Court was requested by a police officer. My evidence on a case of assault was taken, and the prisoner committed to the sessions, when, after waiting four or five days "in durance vile," evidence was again taken, and the case terminated. In the usual course the fees were paid. Mine for attendance at the sessions were at the customary rate; while the sum of half a guinea only was allowed for my attendance at the police court. My residence is *three miles* from the Marylebone Court, and upon this fact rests the grievance which is brought to your notice. A protest to the paying clerk was, of course, useless. There it was down on the expense sheet, and he must abide by it. So also was a letter to the magistrate who heard the charge. This evoked no reply at all. As a last resource, an application addressed to the Secretary of State on the 3rd inst., giving particulars as to date of attendance, and especially distance travelled each way, obtained the following unsatisfactory answer.

Whitehall, 12th November, 1875.

Sir,—With reference to your letter of the 3rd inst, asking for 10*s.* 6*d.* beyond the amount you received as your fee for attending to give evidence at the Marylebone Police Court, I am directed by Mr. Secretary Cross to inform you that the fee which you have received is in accordance with the authorised scale, and that he is unable to order any addition to it.

I am, Sir, your obedient servant,
Edward Shoppee, Esq, Old Chapel House, A. F. O. Liddell.
233, Kentish-town-road, N.W.

It has not been my intention to dwell on the inconveniences medical men are constantly put to in being compelled to waste their time at the different courts they have to attend days before their evidence is required, nor on the inadequate fee they receive, but simply to show the difficulty there exists in obtaining redress even when the claim is, or should be, incontrovertible. That a magistrate's clerk should make an error in the scale of fees laid down by law is not a marvel; but that those in whom high authority is vested should fail to discharge their obligations to private individuals, and mete out common justice, is, to say the least, a matter of regret.

I remain, Sir, your obedient servant,
Kentish-town, Nov. 17th, 1875. E. Collett Shoppee, M.R.C.S. Eng.

⁂ Let us hope that the recent marriage of equity and law will quicken in the authors of "authorised scales" the sense of justice, and reduce the amount of that unalterableness which is so discreditable a feature of many of our own laws, as it was of the laws of the Medes and Persians. The authorities of our Colleges should make joint representations of such grievances to the Home Secretary. We would suggest to our correspondent to draw up a memorial, to be signed by several members of his College, asking the Council of it to make such a representation as we have indicated to the Home Secretary.—Ed. L.

The Artisans' Dwellings Act.

Dr. Tidy, the medical officer of health for the parish of Islington, has reported to the Sanitary Committee of the vestry, for the information of that body, that he deems it desirable to have the provisions of the Artisans and Labourers' Dwellings Improvement Act (1875) applied to no less than 306 houses in the parish, chiefly situated in the courts and alleys adjoining High-street, Islington.

Mare's Milk.

The composition of asses' milk, though deficient in fat by 2 per cent., has always been considered the nearest to that of woman's milk. From Langaard's analysis in Virchow's Archiv (lxv., i.) there seems to be a considerable difference in the casein of the cow's and of the mare's milk. The former is nearly insoluble in water; the latter, especially when in the fresh state, much more so, though not in an equal degree to woman's milk. The chemical reaction on different kinds of acids also shows the casein of mare's milk to be more like that of the human female. Trials of artificial digestion proved both much more digestible than cow's casein. Though the use of mare's milk for infants may be connected with difficulties, the superiority of koumiss made of it over the preparation from cow's milk seems to be pretty clearly demonstrated by the different characters of the two kinds of casein.

J. W.—Our correspondent will find Dr. Johnson's views on bloodletting in inflammatory affections in a lecture published in The Lancet for 1866, vol. ii., p. 685. The work by Dr. Markham is entitled "Bleeding and Change in Type of Diseases" (London, Churchill, 1866), being the Gulstonian Lectures for the year 1864.

The Indian Medical Service.

To the Editor of The Lancet.

Sir,—I observe in your number of the 6th inst. a letter from "A Bird caught with Chaff" on the above subject. I have no personal interest in the question; but as I have lately strongly advised one or two young friends to enter the department in preference to that of the army or navy, it is very likely such letters will be pointed out to me, and some explanation asked as to the assertions therein contained. I have consequently read it over carefully, and would request the favour of being permitted through your columns to say a few words in reference to the subject to young men who are entering the profession.

I would first remark that the writer has no sentimental grievances. They are all reduced to the single category of pay and allowances. I mention this to point out, and emphatically too, that whatever grievances of this kind there were have ceased to exist, or at least do not make themselves felt. As to the money question, it really seems that nothing would content the writer short of the Government guaranteeing him £600 a year for the rest of his life from the date of his landing in the country, together with all additional pay and allowances for length of service. The "unemployed pay" which he speaks of with such contempt is about 10 per cent. less than the Indian pay and allowances of British medical officers of the same standing, and his main grievance is that at intervals for the first four or five years he is reduced to live on that rate of pay. The truth is, that junior men are sent about to supply the vacancies caused by seniors going on leave, until in their turn they secure an appointment for themselves. Again your correspondent states that when furlough is due he can hardly afford to take it. There is an excellent standard to judge this statement by—viz., the pay of British medical officers of the same standing. Accepting that he may be fully two years on "unemployed pay," there are still six years of employed pay before the furlough is due. During this time he will have received from 50 to 60 per cent. more pay than his *confrères* of the army, amounting at the very least to £200 a year surplus—that is, £1200 for the six years,—a very fair sum to find his passage home and out again. The writer omits reference to the half-pay and allowances while on furlough, about £1 a day. So also he says nothing of the huge pickings of a surgeon of the department in India: allowances for railways, civil surgeoncies, lock hospitals, gaols, police, and generally a large private practice. There is just one timid hint at these good things in the complaint of favouritism to natives and half-castes in granting appointments. It shows at least that there are such enviable appointments, and that a man's prospects are by no means limited to the scale laid down in the Government prospectus. The fact is, the prospectus gives only the minimum, and no one of the department is quite satisfied till he gets something better, and, I may add, there are very few who do not. The pensions are certainly small, but only small from an Indian point of view. As men on pension are no longer in active service of Government, they are not paid the tentage, horse allowance, &c., which form large items in Indian receipts, and perhaps, too, the rates are a remnant of the olden time, when they were largely supplemented by pension funds. They are, however, much larger than those of the British medical service. I append a table of rates per diem for comparison.

	After 17 yrs.	After 20 yrs.	After 25 yrs.
Indian medical service ...	12*s.* ...	16*s.* ...	20*s.*
British do. do. ...	Nil. ...	10*s.* ...	16*s.* 9*d.*

Your correspondent's comment is rather amusing that £220 pension will not keep a bachelor in moderate comfort. But who ever expects that the Government would undertake to keep him in affluent circumstances for the rest of his life after fifteen years' actual duty in India, besides paying him very well all the time?

I am unwilling to intrude on your space any reference to the bright side of the picture, and will end by saying, briefly, that those who enter the department have a wide career before them, and the chance of making lots of money; and when they at last retire fairly well off, they will probably find they have not had a day's more foreign service than the average of their *confrères* of the army and navy, who retire with nothing but their small pensions to look to.

Yours respectfully,
November 12th, 1875. Half-pay.

The Meeting of Corpulent Men in America.

The papers of the United States give a description of this meeting, which took place at Gregory's Point on the 25th of August last. If the details are not a little exaggerated, monstrous individuals to the number of about one hundred assembled together, some being brought in carts, as no ordinary vehicle would carry them. The consumption of food at the dinner was, it is said, "miraculous." 100 barrels of oysters, 10 casks of potatoes, 300 lb. of carps, 100 lb. of eels, 300 lb. of lobsters, besides mountains of meat of various kinds. The beverage was beer, of which 300 barrels were drunk. Would not these people be highly benefited by a course of "Banting"?

The Insane in the Department of Seine.

This department, of which Paris is the capital, had to provide in 1801 for 946 insane persons. On the 31st of December, 1874, they had increased to 7072, being sixfold the former number, whilst the whole population had augmented only threefold. For the last ten years the mean increase of the insane has been 200 per annum. Up to 1860 the female sex was in the majority; from that period the men have outnumbered the women. At the present time there are, out of 1000 insane, 542 men and 458 women. Among 2177 patients who were admitted in 1874, 882 were single, 855 married, and 348 widowers or widows. As regards the callings of these patients, we find that 853 were engaged upon manual labour, 332 had no occupation, 302 were servants or in the employment of others, 263 carried on trades or commerce, 120 belonged to the liberal professions, 36 were landed proprietors or independent, and 19 belonged to the army and navy. Among the causes of insanity, intemperance amounts to 37·22 per cent. of all the cases. In the year 1874 the insane of the department of Seine cost £163,096.

Epsom College.

To the Editor of The Lancet.

Sir,—Will you have the kindness to extend the ægis of your protection over the medical officers of the above institution, and, by publishing the enclosed letter, spare us if possible from a similar infliction in future.

My partner, Mr. Jones, of Epsom, and myself were recently appointed medical officers to the Royal Medical Benevolent College at Epsom, and having one or other of us devoted between two and three hours each day to its duties, I can conscientiously say that neither attention, time, nor *medicine* have been spared—even to the sacrifice of private work—in fulfilling them. If in the management of such a simple affair as a case of chicken-pox we are not only to have our treatment questioned, but are expected to write to parents in self-defence, the duty would be endless, and too irksome to be encountered.

I forbear to comment on the letter itself.

Yours very truly,
November, 1875. Geo. R. Barnes, M.D.

[copy.]

———, November 11th.

Dear Sir,—Hearing that my youngest boy at Epsom College was suffering from chicken-pox, and had been confined to the room for a week, I went down to see him, and I was surprised to find that he had no medical treatment, and that during the fortnight he was up there he had not had any medicine given him. Now, I consider if he had the usual medicine given in these cases, he would have recovered more quickly, and I certainly do not approve of *this do-nothing treatment*, when I think a little medicine would have greatly relieved; even gentle aperient doses, with saline and diaphoretic medicine, I consider very much relieves the skin affection, and I frequently find it leaves children weak for some time afterwards, requiring a tonic medicine. I now hear that he has been obliged to leave the school again, in consequence of a boil or abscess on his neck. I should be glad to hear from you what it is, and if I find his health in a bad state I must consider whether I shall take him away from the school. It is most inconvenient to me to come so long a journey just now; therefore I am anxious to know what is being done.

Yours truly,
To Dr. Barnes. * * * * *, F.R.C.S. Lond.

Overseers' Orders on Medical Officers.

To the Editor of The Lancet.

Sir,—I shall be glad if you will kindly give me your advice on the following subject. On March 31st, 1875, an overseer of my district gave an order for me to attend a man. I found him suffering from fractured leg (tibia). I attended him, and he went on well. On rendering my half-yearly account of extras to the guardians, they refused to pay this item, alleging that the patient himself was in a position to pay. Now, Sir, whom must I sue for my fee—the guardians, the overseer, or the patient?

I am, Sir, yours faithfully,
Whitwick, Leicester, Nov. 15th, 1875. C. J. B. Johnson.

*** An overseer can give an order only in cases of *sudden* and *urgent* necessity, and the medical officer is only required to attend upon the overseer's order in such cases. If he attend upon any such order, and the case be not of that nature, the medical officer may have a claim against the overseer, but has none against the guardians. Cases of fracture, supposing the patient to be very poor, seem to come fairly under the category of sudden and urgent cases, and we should advise our correspondent to press his claim on the guardians, unless, indeed, the man's circumstances clearly indicate his own ability to pay, in which case we should advise that the overseer be sued, leaving him to recover from the patient. At the same time we advise all medical officers under the Poor Law not to receive overseers' orders, except in cases at once urgent and sudden.—Ed. L.

"Amocque."

To the Editor of The Lancet.

Sir,—The disease termed "amocque," which Dr. Adams refers to in your last number, and described by the captain of a ship as "a form of ringworm attended by madness of more or less severity," was, in all probability, that form of homicidal mania produced by the inordinate use of haschish, bhang, or Indian hemp (Cannabis indica). This form of madness has of late years been frequently described in medical journals and books of Eastern travel, and its Malay name has been Anglicised to denote a mad indifference to the result of bad actions (seen sometimes nearer home than Siam)—viz., "running a muck"! (amocque).

The "ringworm" I look upon as no essential part of the disease, but was probably that parasitic affection called "dobie itch," well known to Europeans on the China station, and which, in the natives, becomes sometimes so intolerable as to induce them to take large quantities of "bhang" in order to obtain relief.

I am, Sir, yours faithfully,
Gosport, November, 1875. Robert Nelson, Staff Surgeon, R.N.

The Royal Society.

The award of the medals in the gift of the Society for the present year, by the Council, is as follows:—The Copley medal to Prof. A. W. Hofmann, F.R.S., for his numerous contributions to the science of chemistry, and especially for his researches on the derivatives of ammonia; a Royal medal to Mr. William Crookes, F.R.S., for his various chemical and physical researches, more especially for his discovery of thallium, his investigation of its compounds and determination of its atomic weight, and for his discovery of the repulsion referable to radiation; a Royal medal to Dr. Thomas Oldham, F.R.S., for his long and important services in the science of geology.

N. S. P.—Apply to Letts and Co., Cornhill.

Low Death-rates.

To the Editor of The Lancet.

Sir,—In the "annotations" in your issue of Nov. 6th, I notice your remarks on a supposed Hygeiopolis in Wiltshire, wherein you demolish the figures of the medical officer of health for Bradford-on-Avon; but to show that it is possible to come near such a low death-rate (and without the possibility of demolishing my figures), I am pleased to state that our death-rate for the three months ending Sept. 30th, 1875, was at the annual rate of 9·6 per 1000, our population being 11,111, with 27 deaths in the three months; and I am the more gratified in being able to do so, because I feel that certain erroneous ideas existed concerning the general salubrity of this town in consequence of its late unfortunate epidemic, which, by-the-bye, happily left us five months ago. That the town is a healthy one may be gathered from several circumstances—viz., the many instances of extreme longevity among the inhabitants, the comparatively low infant mortality, the freedom from epidemics (the late one being the first in the recollection of the oldest inhabitants), and the generally low death-rate, 18·24 being the average for the three years 1872–74, that for 1872 rising only to 16·47.

I am, Sir, yours obediently,
J. G. Braden,
Lewes, Nov. 11th, 1875. Medical Officer of Health for Lewes.

To the Editor of The Lancet.

Sir,—In your impression of the 6th inst. you refer to a supposed Hygeiopolis in Wiltshire, with a death-rate of 7·5 per 1000. I have one in my combined districts of only 6·7 per 1000 per annum for the quarter ending Sept. 30th, 1875. During the same period the birth-rate was 43·1 per 1000. The population in 1871 was 3341, and I estimate it for the middle of 1875 as 3550. It is the urban sanitary district of Warley, situated near Halifax, in the West Riding of Yorkshire, the inhabitants of which are principally engaged in mills. I am, Sir, yours faithfully,

Thos. Britton, M.D.,
Halifax, Nov. 12th, 1875. Medical Officer of Health.

Nuisance from Gas.

Dr. F. E. Wilkinson medical officer of health for the district of Lewisham, in a report recently issued, describes a somewhat unusual nuisance which came under his observation last year:—

"There was a most offensive nuisance in November last for several days, causing great alarm in the neighbourhood of St. Germain's-road, Catford, and Lewisham. It was occasioned by large volumes of sulphuretted hydrogen gas which escaped from the sewer in the night, and were traced along the Ravensbourne and Sydenham main sewer, in the Bromley and Lewisham road, from the turning to Ladywell to the 'Black Horse' public-house, Rushey Green, and from thence along the Catford road to the Crystal Palace Gas Works, Bell Green. This gas entered the houses along the line of sewers through the sink traps and pipes, and discoloured the white paint in many houses and turned the silver black, and some of the inhabitants had to turn out into the streets. As soon as this disgusting nuisance was traced to its source, proceedings were taken to stop it, both by the Metropolitan Board of Works and the Lewisham District Board of Works, against the Crystal Palace Gas Company. The directors of the Company denied that anything had been done at their works to cause a nuisance; but upon being served with notice of the Lewisham Board's intention to apply to the Court of Chancery, the nuisance immediately ceased; and on the hearing of a summons, issued by the Metropolitan Board against the Company, the magistrate inflicted a fine upon the Crystal Palace District Gas Company of 40*s.* and costs."

Physiologist, (Birmingham.) — Our correspondent probably refers to the observations of M. Paul Bert, which are noticed at some length in The Lancet of May 30th, 1874.

Treatment of Incontinence of Urine.

To the Editor of The Lancet.

Sir,—In the treatment of incontinence of urine I have found that belladonna acts well for very young children; but with boys over eleven or twelve years, who have retained the infirmity, no treatment has answered so well as a combination of belladonna with creasote, in the form of a pill, as follows:—Extract of belladonna, twelve grains; creasote, twenty-five drops; oil of cinnamon, four drops: made into a mass with bread-crumbs, and divided into fifty pills, of which one should be taken after dinner, and one shortly before going to bed. I have never known this to fail with boys, who are generally cured in about three weeks from the time they begin the medicine. Yours obediently,

Marlborough College, Nov. 16th, 1875. Walter Fergus.

Calabar Bean.

To the Editor of The Lancet.

Sir,—A leading oculist has told the friends of a patient who is using an eye drop of Calabar bean (one to thirty of water) for neuralgic (?) headache with great benefit, that such treatment is dangerous to the eye. Since reading Dr. Munro's cases of tic cured by this method, I have had unvarying success in several obstinate cases, and have never seen ill-effects. Still, as the oculist in question considers the treatment eccentric and dangerous to the eye, I should be glad to elicit the opinion of the profession upon the subject. Yours &c.,

November 13th, 1875. M.D. Lond.

A New Danger.

Dr. Whitmore, medical officer of health and analyst for Marylebone, reports that he very recently analysed the colouring matter contained in four pieces of tarlatan, a material worn by ladies as evening dresses. Two of the pieces were of a bright green colour, the other two of a pale or apple green. Those of the bright green colour contained arsenic in considerable quantities, one of the pale green contained a minute trace of it, but in the other none could be detected. He was induced to make these analyses from having heard that two young ladies had suffered from symptoms of arsenical poisoning in consequence of having worn dresses of this description at an evening party, and he proposes to make further analyses of a similar kind, the results of which will be given in his next quarterly report.

A Dangerous Lunatic at large.

To the Editor of The Lancet.

Sir,—Will any of your readers be good enough to advise me how to act in the following case.

A powerful man, in a neighbouring village, has been confined eight separate times in the County Asylum (as a pauper), and each time after a few months' residence has been discharged "cured," to be returned in a few months as a dangerous lunatic. The last three times before he was removed he kept the village in terror for hours, once stalking up and down it, armed with a loaded double-barrelled gun and a meat-chopper, and the two last times inflicted considerable damage on the relieving officer before he could safely lodge him in the asylum; so much so that when he removed him six weeks ago he was much bruised about the head and face, and has still a swollen and stiff finger. Even at his best times there is generally something in his manner which marks him as not quite sane, and, in my opinion and in that of my partner, he ought to be permanently confined. Can any steps be taken to attain this object, and, if so, how must I proceed?

Yours faithfully,

Eye, Nov. 17th, 1875. Edgar G. Barnes, M.D. Lond.

Mr. Young again.

Mr. Charles Young is not yet happy, as the following advertisement from the *Western Gazette* shows:—

> "Charles Young, Surgeon, Chilton Polden, although endeavouring to obtain another practice, hopes to attend his patients until he leaves, and to have the privilege of remaining, should he desire it, which is most likely."

Communications not noticed in the current number will receive attention in our issue of the ensuing week.

Communications, Letters, &c., have been received from — Prof. Parkes; Mr. Bryant, London; Mr. Simon, London; Mr. Teevan; Mr. Rivington, London; Dr. G. MacLeod, Glasgow; Mr. Braden, Lewes; Mr. Griffiths, Cardigan; Mr. J. Farrar, Bradford; Dr. Philipson, Newcastle-on-Tyne; Dr. Neate; Dr. Griffiths, London; Mr. Whines; Mr. G. Cowell, London; Mr. C. Medical Diary for the ensuing Week.

Monday, Nov. 22.

Royal London Ophthalmic Hospital, Moorfields.—Operations, 10½ a.m. each day, and at the same hour.

Royal Westminster Ophthalmic Hospital.—Operations, 1½ p.m. each day, and at the same hour.

St. Mark's Hospital.—Operations, 9 a.m. and 2 p.m.

Metropolitan Free Hospital.—Operations, 2 p.m.

Medical Society of London.—8½ p.m. Dr. de Havilland Hall will exhibit a Pathological Specimen of Tumour of the Liver; Dr. Thorowgood, a Specimen of Cirrhosis of the Liver in a Child, and a new Inhaler and Respirator by Mr. Carrick, of Glasgow.—Dr. Brunton, "On the Rational Treatment of Tapeworm."

Tuesday, Nov. 23.

Guy's Hospital.—Operations, 1½ p.m., and on Friday at the same hour.

Westminster Hospital.—Operations, 2 p.m.

National Orthopædic Hospital.—Operations, 2 p.m.

West London Hospital.—Operations, 3 p.m.

Royal Medical and Chirurgical Society.—8½ p.m. Dr. Pavy will exhibit a Specimen of Sugar obtained from Healthy Human Urine, and prove its existence by the appropriate tests. — Mr. F. H. Welch, "On Aortic Aneurism in the Army, and the conditions associated with it."

Wednesday, Nov. 24.

Middlesex Hospital.—Operations, 1 p.m.

St. Mary's Hospital.—Operations, 1½ p.m.

St. Bartholomew's Hospital.—Operations, 1½ p.m., and on Saturday at the same hour.

St. Thomas's Hospital.—Operations, 1½ p.m., and on Saturday at the same hour.

King's College Hospital.—Operations, 2 p.m., and on Saturday at 1½ p.m.

Great Northern Hospital.—Operations, 2 p.m.

University College Hospital.—Operations, 2 p.m., and on Saturday at the same hour.

London Hospital.—Operations, 2 p.m.

Samaritan Free Hospital for Women and Children.—Operations, 2½ p.m.

Thursday, Nov. 25.

St. George's Hospital.—Operations, 1 p.m.

Royal Orthopædic Hospital.—Operations, 2 p.m.

Central London Ophthalmic Hospital.—Operations, 2 p.m., and on Friday at the same hour.

Friday, Nov. 26.

St. George's Hospital.—Ophthalmic Operations, 1½ p.m.

Royal South London Ophthalmic Hospital.—Operations, 2 p.m.

Clinical Society of London.—8½ p.m. — Dr. Murchison "On a Case of Acute Cancer of the Liver, with Pyæmia, in a Man aged twenty-four"; "On two Fatal Cases of Acute Pyelitis and Nephritis apparently consequent on Gonorrhœa."—Mr. Berkeley Hill, "On a Case of Amputation at Hip-joint for Fibro-plastic Tumour."—Mr. Geo. Lawson, "On a Case of Melanotic Tumour of Orbit."

Saturday, Nov. 27.

Royal Free Hospital.—Operations, 2 p.m.

Charing-cross Hospital.—Operations, 2 p.m.

TERMS OF SUBSCRIPTION TO THE LANCET.

PART OF A

Lecture

INTRODUCTORY TO THE COURSE GIVEN AT

UNIVERSITY COLLEGE HOSPITAL,

Delivered on November 15th, 1875.

BY SIR HENRY THOMPSON,

SURGEON EXTRAORDINARY TO H.M. THE KING OF THE BELGIANS; EMERITUS PROFESSOR OF CLINICAL SURGERY IN UNIVERSITY COLLEGE HOSPITAL.

(*Reported by* MR. G. BUCKSTON BROWNE.)

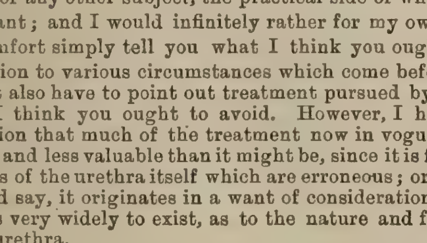
AFTER a few words of introduction, expressive of the pleasure which it gave the lecturer to return to the scene of his former labours for a short time, he defined the nature of the course and its scope, alluding to various minor points in connexion with it. He then said:—

In view of a consideration of the more important affections of the urethra, with which I shall naturally commence, I desire to depart from my usual habit a little to-day, and to speak more at length on a topic which I always allude to slightly, but not otherwise, because it is not part of my plan to teach anatomy and physiology here. But I find it necessary to complain of what I will speak of as the "too mechanical method" of treating urethral diseases, which I think has been obtaining of late in some parts of the Continent, and perhaps in America. What I mean by that will appear as we proceed. I always protest against it in this course of lectures, but something more than this appears to me now to be desirable. I dislike to be polemical in this or any other subject, the practical side of which is so important; and I would infinitely rather for my own peace and comfort simply tell you what I think you ought to do in relation to various circumstances which come before you, and not also have to point out treatment pursued by others which I think you ought to avoid. However, I have the conviction that much of the treatment now in vogue is imperfect and less valuable than it might be, since it is founded on views of the urethra itself which are erroneous; or rather, I should say, it originates in a want of consideration, which appears very widely to exist, as to the nature and function of the urethra.

The treatment of urethral disease of which I complain has its origin in the notion that the urethra is a mere flexible tube, closed at or near its junction with the bladder by some kind of muscular apparatus, sphincteric or otherwise, through which fluids will pass indifferently in either direction. No idea, however, can be more erroneous, and treatment founded on it must be defective.

At the outset, then, let me say that it is absolutely essential that you should have a tolerably accurate knowledge of the nature and functions of this so-called tube.

I draw for you on this board the kind of diagram usually supposed to represent the bladder and male urethra. This diagram has something to answer for in producing the erroneous views I refer to. It represents the urethra as a tube, and as more or less open.

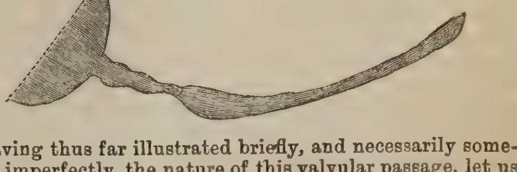


Let me give you an illustration of my meaning, and not an unimportant one. I believe I am correct in stating that almost every patient who presents himself for treatment of a urethral discharge, when advised to use an injection, gets some such advice as this, when the manner of doing it is explained, as it ought to be, in detail:—He is told to inject a certain quantity of liquid into the passage by means of a syringe of some kind, and in doing so he is always admonished to make pressure on the line of the urethra, some four inches from the orifice, in order to prevent the fluid from passing beyond that point, and so perhaps enter or irritate the ducts which open into the prostatic portion, and occasion irritation of the neck of the bladder or a swelled testicle—an idea which is far from correct; and such advice simply demonstrates that the person giving it is not really acquainted with the structure or function of the part he is treating. Want of thought originally has produced, and the influence of ancient tradition perpetuated, the error which vitiates much of our treatment in its various forms.

First, let me assure you that the urethra is not a tube at all, in any sense in which we employ that word. It is not like a gas-pipe, or an india-rubber tube, or even a flaccid tube of any membrane whatever.

It is rather *a continuous closed valve, capable of transmitting fluids and solids in one direction only, and transmitting nothing whatever in the opposite direction, except in obedience to applied force.* Its length in the male makes us think of it as a tube, but this is a mere accident of sex. An inch or less is amply long enough for its urinary function, as in the female; and all the length it possesses above that is quite useless *as a urethra*, and renders it liable to disease and accident—the price, and a heavy one, let me tell you, which the male pays for his specially distinguishing feature. In illustration of this, I have but to refer you to the innumerable difficulties and dangers associated with stricture, retention of urine, and calculus, which are almost unknown in the other sex. It is, then, in the male simply a long valvular chink, traversing soft and most delicate vascular and nervous tissues, always firmly closed, and never opening except for a few seconds, during which fluids have to be transmitted from the body. Then, for a few seconds, it is distended more or less, and becomes a tube if you please, for this short time and this only, equalling, perhaps, at most three minutes in the twenty-four hours. All the rest of the time it is firmly closed, and not one drop of fluid can pass from the bladder. Of course, oozing of liquid which is generated in the walls of the tube, or which enters it by ducts may escape, but always, inevitably, in the outward direction only.

Now, during these few seconds, when the valve may be said to occupy the form of a tube, I have next to observe that it is a tube of very varying diameter in its different parts; it is, in fact, very differently distensible at different places, being surrounded by different structures. This fact has long been known and generally recognised. I will show you illustrations of this from the works of Sir Everard Home and of Mr. Guthrie, who made casts of it in wax and other materials. This point is scarcely of less importance than the preceding one. The annexed diagram is reproduced from Sir E. Home's work.*



Having thus far illustrated briefly, and necessarily somewhat imperfectly, the nature of this valvular passage, let us see how far the ideas which I want you to acquire relative to the urethra affect two important points in practice. First, that simple matter of making an injection into the urethra. You have to introduce a fluid for the purpose of therapeutic contact with the walls of this closed passage; you have to distend it, and some little force is necessary; not a single drop can enter, much less run down into it, unless the liquid is forced in by a piston, while the orifice of the urethra is carefully closed around the tube of the syringe introduced. The walls of the passage lying closely applied to each other become opened only by the pressure of the fluid driven in, and they are distended just so much and so far as the quantity employed determines. Thus you may safely reckon, as the result of my observation, that a syringe containing one fluid drachm is amply sufficient, and that it will distend the urethra for three and a half or four inches. A half-drachm syringe often suffices. Here is one of each size, and it is scarcely necessary to say that these small instruments are much more easily managed by a patient than larger and longer ones. But most patients, unless specially taught to use the syringe, never introduce any injection at all. Unless the orifice of the urethra is carefully closed at the time, the fluid simply leaves the end of the syringe and flows out by the external meatus; and in every case after the injection has been made, the moment the orifice is unclosed the fluid is rapidly expelled by the contractile force of the urethra, and no appreciable quantity remains within. So much, then, for any fear of its running down to the neck of the bladder. Of course, if an injection is too strong—in my opinion a very frequent occurrence,—the anterior part of the urethra is inflamed, and extension backwards may easily take place; but that is no part of our subject now. But let me further say that, so far from your being able, even with the power of the syringe, to send an injection into the prostatic part of the urethra, you cannot do so by any ordinary force, unless you can at the same time voluntarily relax the muscles which surround the membranous urethra, and so allow the fluid to pass—a thing perfectly possible with very little practice to accomplish. Thus it is that you cannot inject the bladder except by passing an instrument into its cavity. In fact, this valvular passage stoutly resists all intrusion from without, and admits no fluid except in obedience to pressure which it is unable to resist.

---

* Practical Observations. By Sir E. Home. Vol. I. London, 1805.

I must just remark, in order to anticipate a possible objection to my statement relative to the valvular action of the urethra, and its power to transmit bodies in the outward direction only, that it is well known that certain foreign bodies have been able to pass inwards when introduced by the external meatus. I refer to two typical ones, both of which have been occasionally known to reach the bladder after being fairly lodged within the urethra. I refer to an ear of barley or of rye, both of which you will recollect are bearded, and also to a common hair-pin, which is wedge-shaped. Either of these bodies, if completely introduced, and also in such a manner that the beards or the points are directed outwards, will traverse the urethra in the direction inward. These, however, you will doubtless at once see are not in the least degree exceptions to my statement. It is an old schoolboy's paradox to put an ear of rye in his jacket-sleeve, when, with slight movements of his arm, although directed downwards, the ear soon finds its way upwards to his shoulder. If the arm was kept perfectly motionless there would be no change of place in the ear of rye. So, when introduced within the urethra, the involuntary movements of the urethral muscles, designed to expel the intruder, act on the ends of the bearded corn, or on the ends of the hair-pin, and drive it on in the only direction it can travel—namely, inwards. I am not sure that it was necessary to mention this, but I have known the peculiar action of these bodies referred to as militating against the uniformity of the action of the urethra referred to, while in fact they do but illustrate its existence. If the urethra submitted tranquilly to the intrusion, and made no expulsive effort at all, the foreign bodies would not travel; as it is they must move, and can only do so in one direction. Of course it is due to this function of the urethra that gravel and small calculi are expelled in great number, and that the morbid excretions in gonorrhœa, &c., always issue externally, and never go backwards to the bladder.

The second point of importance in which the structural function of the urethra which I have described should affect our practice is associated with treatment of stricture of the urethra. I do but allude to this now, and shall reserve what I have to say on this head until a future lecture, when I shall enter fully on the subject.

From the Report on the Sanitary Measures in India in 1873–74 we learn that the general death-rate in the European army in India in 1873 was 15·3 per 1000, a lower rate by upwards of 2 per 1000 than any previously recorded. If deaths of invalids returned to Netley are added, the rate is 15·8 per 1000.

Introductory Lecture
TO THE WINTER COURSE OF
CLINICAL SURGERY.

Delivered at the Western Infirmary of Glasgow
(University Clinic),

By GEORGE H. B. MACLEOD,
REGIUS PROFESSOR OF SURGERY, SURGEON AND LECTURER ON CLINICAL SURGERY IN THE INFIRMARY.

Gentlemen,—It is desirable that at the outset of our clinical work I should explain to you the nature of the study we are going to engage in, and the system of teaching it which I pursue. Within the University I have already made known to you the aim and scope of my course of instruction in systematic surgery, and now here, in our practical school, I desire to point out what further duty devolves upon me as your teacher. As Professor of Surgery in this school, my business divides itself into two parts. These are not distinct or independent, but, on the contrary, form one whole, and that consists in a complete course on the science and art of surgery. One half of my function I perform within the University, and the other half here in the hospital. No systematic course can be complete without its practical part in the clinical school, no more than systematic anatomy or chemistry can be efficient without dissecting room and laboratory. On the other hand, no bedside instruction can avail without preliminary education in the class-room. I am desirous of placing thus clearly before you this entire affinity and relationship between what is termed the theoretical and practical departments of my subject, as attempts are occasionally made to dissever them, and even to exalt the one at the expense of the other. That of late years a strong disposition should have manifested itself to depreciate "lectures" and all mere oral teaching, and to commend "practical" instruction, need not astonish us when we remember how terribly lecturing was abused in days not long past. It appears to us now almost incredible that anatomy, chemistry, and botany should at one time have been taught without practical illustrations, but there is no doubt they were so. It must be borne in mind, however, that such practical instruction in surgery as can be given here is only capable of supplying you with a certain amount of that learning which you require. It alone cannot possibly equip you for the exercise of the surgical art. You cannot do without it, yet you cannot do everything by it. It is requisite that you be first instructed in the principles on which the practice seen here is founded. You must be made conversant with the terms used at the bedside. You must know in some measure the nosology and pathology of the diseases brought before you, as well as the usual influence exercised by those conditions which are special to the patient, and the effects which are produced by remedies. Systematic surgery is, after all, the sum of clinical experience. Such a course is made up of the conclusions or generalisations drawn from a multitude of bedside observations reduced to order and systematised. Clinical surgery can thus never wholly take the place of systematic, but must ever be auxiliary and subsidiary to it. The two branches must be entwined, and then they will mutually support and illustrate one another. If you have been well instructed in principles you will come half taught to the bedside, and be capable of profiting by what you there see. To learn practical surgery, however, is not easy, and will demand all your attention. Give it as much time as you can. It is by it that you must come to fulfil the chief end of your professional career, the alleviation of suffering and the saving of human life.

Clinical study, then, aims at applying the rules and doctrines of the class-room to actual cases of disease. In the hospital we see the living illustrations of those affections which we have heard or read of, and in many cases we are able to compare the relationship which exists between certain signs seen during life and the state of textures and organs after death. It is in clinical research, properly conducted, that we gain that accuracy in the employment of the special senses which is so desirable, and learn to exercise the judging and reasoning faculties in sifting evidence and separating what is accidental and immaterial from the essential and important in those facts or signs which are presented to our observation. Careful attention, patience and diligence, truth and candour in observing and applying facts to theories, accuracy in generalising or deducing principles, these are qualifications which are requisite in a true clinical student.

In this school, as in most others, clinical instruction is conveyed both by lectures and bedside teaching. Once a week a more formal lecture is given by each medical attendant, and on several days you receive instruction in the wards. Both these methods are advantageous when combined. In some schools the bedside work is neglected, and the lecture becomes the main or sole means of teaching, while in other hospitals the reverse is the case, and ward lessons are alone employed. The traditions and usages of the school, or the means and time at the disposal of the teacher, appear in many cases to determine the choice. I do not think that in many schools this practical work has been so zealously cultivated as it has been for some years here. You will soon find how strictly attendance is enforced. At five minutes past nine in the morning, whether it be at lecture or in the ward, the roll will be called, and every absentee must give a satisfactory account of himself. I shall endeavour this session, as in the past, to be at my post every morning to a moment, and to allow no private engagement to interfere with this important duty, and I shall expect from you like diligence and punctuality. I want no sluggards here, and none who, by careless attention, disturb the application of others. Every man of you must act as dresser, either now or in summer. I will give every facility for a long continuance of that service. It is as a dresser that you will come to have a true interest in the patients, to observe their cases with care, and feel some part of the difficulties and responsibilities of the work.

After studying the various plans of clinical teaching followed in other schools at home and abroad, the method I have been led to adopt is this. On Monday, my friend Dr. Knox (one of our assistant-surgeons, and able demonstrator) will give you in the side ward minute instruction in bandaging, dressing, and the application of surgical apparatus. This duty I used myself to perform, but I am glad to have it taken up by younger and abler hands. What is there shown you will individually have to repeat before your instructor, and afterwards in my presence, in the fulfilment of your duty as dressers. All dressings of any consequence, as well as apparatus for fractures &c., are applied either by you or in your presence by myself or my house-surgeon. It is quite impossible that any accident can prevent, as too often happened in my own time, a student who attends the wards regularly from seeing all the usual fractures and dislocations frequently dealt with in all their details. On Tuesday I meet you in the theatre and "lecture." By this I mean that I then dwell upon the lessons derivable from a series of cases of the same affection which either at the moment are or quite recently have been under treatment before you; or a wider and more general view than can be taken by the bedside is given of some of those accidents or diseases we have been studying,—a view checked and regulated, however, at every point by the example of it we have been dealing with. At other times the causes, nature, and results of an operation recently performed, or some more general affection affecting the sick under our care, are taken up. Cases of the same disease in different wards are, as it were, collated and compared, and what practical lessons they teach enforced. In this part of the work pathological specimens and drawings are occasionally employed; yet it is most desirable, even in these more formal meetings, to avoid controversial and critical discussion as much as possible. On Wednesday, Thursday, and Saturday we meet in the ward. Friday being the lecture day of my colleague, you are excused attending with me (as his students are on Tuesday), in order that you may be present at his "lecture."

My ward work is thus conducted. We have a side room, well heated and lighted, fitted up with seats and a bed, into which all those patients who can be moved are brought on a light, noiseless, easily-wheeled couch. If a patient cannot leave his bed, then we visit him in the ordinary way; but I much prefer having patients taken into the side room, because they can be there seen and examined with more care and attention. Every student, being seated, can give his full attention to what is doing, and can take notes accurately and comfortably. The patient is placed on the bed in the full view of all, and his ailments are systematically inquired into. You will observe that I put each question in a loud voice, and that I repeat the reply, so that you can all follow what is doing. After a little initiatory practice, you will each be called upon to take my part and examine the patient. I shall in any case try to show you how best to obtain and apply information; and I shall, by examining you on what you see and hear, know whether your comprehension follows the work performed. Explanations can be given regarding each case both before the patient enters and after he leaves. All remarks which it is undesirable that he or his fellows should hear can thus be freely given utterance to, and so all fear of wounding his feelings avoided. The harm, too, which so frequently is done to weak and nervous patients by the rush of an eager crowd into the ward is prevented, and thus the interests of both patients and students are promoted. The lesser operations I also perform at these meetings; and as you are close to the patient, and each step is explained, you will, I think, get more good from them than is usually attainable. Great and dangerous operations unfortunately require not unfrequently to be undertaken, but these you will see performed in the theatre on Saturday. In this hospital I hope you will not find any of that ill-placed sensationalism regarding operations which, to the great detriment of students and the profession, is too often indulged in. Our aim should always be, to diminish the number and lessen the risk of those operations which mark surgical practice.

The cases we shall chiefly deal with in our ward work are the common and every-day surgical ailments, not the rare and curious, which seldom occur in actual practice. The more usual an ailment or accident, the more claim it will have upon our attention. Each morning we will only take up a very few cases, and these typical and well-marked examples of their kind. The great point will be to secure a clear comprehension of a few ailments at a time, and the principles deducible from them. All risk of such confusion as would arise from dealing with too many, and, above all, unrelated cases, must be avoided. Here we have always abundant material from the large and busy city around us. I shall try to be as simple and elementary as possible in conveying information, remembering that the receptivity of first-year's hospital students cannot be great; and I shall also aim at rendering the whole teaching as conformable as possible to a system, so that by the end of the session we may have compassed a fair summary of surgical practice. We must so group our cases as to make them afford the greatest amount of instruction, and at the same time secure order in our work. To accomplish this effectually, two things are provided. I have put into your hands a short guide to case-taking, in which you will find an outline of the chief points to be observed, both as regards cases in general and special ailments. By following this a uniform system will be attained. The other acquirement to orderly procedure is that I keep a daily register of what we do in the wards, so that an easy control is maintained, and, in a great measure, a definite arrangement followed out. I shall expect every dresser to have an intimate acquaintance with his cases, and occasionally I shall ask for written reports from him, besides questioning him at the bedside. Rewards (medals and certificates) are given for diligence and proficiency, and the house-surgeonships are bestowed (if the applicants are otherwise eligible) on those who attain the highest place in this department.

But, besides the junior class, to whose studies I have been hitherto referring, I have been induced by the spontaneous request of the senior men (those who have passed on to the medical side of the hospital) to meet them once a week for clinical purposes; and I would here for a moment speak of that class, as it is a voluntary one, and beyond doubt the most useful I have ever conducted. This is the third year of its existence, and this session it contains the great majority of the most advanced students. The hour of meeting is after the usual visits on Thursday, and for their instruction I chiefly employ the out-door patients who come to my ward for advice. In the side room we hold our conferences, which are as nearly as possible the same as they would be in private practice. Each student in turn examines a case, and gives an account of everything connected with its anatomy, physiology, pathology, and surgery. Not only do they in this way get their knowledge corrected, but they discover what subjects they are ignorant of, and so are led to supply the deficiency. The utmost frankness of communication is cultivated. These students have also, at my suggestion, organised themselves into a society, which meets on Saturday. Two examiners from their own numbers are appointed for the subsequent meeting, whose duty it is to prepare themselves thoroughly on some medical subject which has been within the range of their study, and for half an hour each presides and examines the rest. Of course he does not let the subject he is going to take up be known beforehand, and his authority for the time is strenuously maintained.

Now, gentlemen, in all this I have frankly laid before you the plan of clinical teaching I pursue, but it will prove fruitless unless it receives your most cordial support. The knowledge you seek must be conquered by yourselves. All I can do is to point the way as best I can, and try to awaken your observing faculties and lead you to reflect. I cannot give you perseverance and attention, but I can and will give you an example of industry and punctual attention to my duty. It is essential to your advancement that you keep yourselves abreast of the cases. You may visit the wards freely during the morning; and the ward journal, in which all changes in the condition of the patients are noted, is open for your inspection; and I shall at each visit tell you carefully of everything which has occurred during the interval since our last meeting. Everything done is open to your most minute inspection. Every error or oversight made you have the amplest means of discovering, and I promise you that they will be frankly admitted and discussed. Candid criticism is the best security against the repetition of mistakes, and gives a guarantee for future improvement.

To get the utmost good from your hospital work, you should read up at home on the different diseases examples of which have been shown you in the morning; and to facilitate this I will at the end of each day's demonstration mention to you the subjects you should thus seek further information on.

It is no use to begin all this work which I have outlined to you with spirit, and let the effort soon die out. The early enthusiasm must be sustained. Steady perseverance is far better than spasmodic application. The sooner students begin to get accustomed to hospital work the better, and the longer they keep to it the more they will like it. I have always regretted that foolish craving for "settling down" in practice which seizes so many of our men after they have graduated. It is just then, when they are free from the phantoms of examinations, that hospital attendance becomes really valuable; and a year of quiet study at that time, in such an institution as this, would, as a mere commercial venture, repay them well, putting out of account the incalculable satisfaction it would prove in after years.

Every morning, I may add, I shall remain fully two hours with you, and nothing will afford me more pleasure than to answer any questions you have to put, or to assist you in any difficulty. My staff of assistants is more than usually numerous, and on their aid you can always rely.

In what time remains to me, I propose to give you a brief outline of the history of clinical surgery, and explain to you the present position of the teaching in this school.

As might be expected, very little is known of the early history of clinical teaching. It is generally said Hippocrates took his pupils to the bedside for instruction; and his careful annotations of disease at least prove him to have been a careful clinical observer. In the Alexandrian school Herophilus and Erasistratus get the credit of having given bedside lessons; but nearly all trace of such teaching is lost from that early time down to the end of the sixteenth century. True, it is said that Thessalus and Symnachus during the first century, and the teachers in the school of Salernum in the twelfth century, attempted such instruction; but our knowledge of its exact nature is too slight to enable us to form any opinion concerning it. For a brief period at the end of the sixteenth century clinical teaching was pursued at Padua and Pisa, but it was soon abandoned; but afterwards, in 1764, a Clinical Chair was established at the former school. In the sixteenth century Medicine was much oppressed by the authority of the ancients. The dogmas of the "Fathers"—Hippocrates, Galen, and Celsus,—held men's judgments in all-powerful fetters till the awakening which followed the Reformation, and the discovery of printing stimulated medical like all other knowledge. Anatomy was in a great measure born, and her eldest child—Surgery—grew to a certain degree of vigour, mainly through the guidance of Ambrose Paré (a pupil of Fallopius), who had the courage to think for himself, and to add his own observations and reflections to the traditional teaching of the schools. He, though, like most of his distinguished contemporaries and successors, a "barber-surgeon," gave surgery somewhat of a scientific position. He established a school of surgical practice which for a hundred years governed France, and, in fact, Europe. The seventeenth century marks the division between ancient and modern practice; and, under the influence of the philosophy of Bacon and Descartes, men's minds began to open, and the all-powerful effect of authority was abolished. Harvey and a host of able anatomists in all countries by their discoveries greatly advanced medical science, while Leeuwenhoek opened up the vast field of minute anatomy by the application of the microscope to histological purposes.

In the middle of the seventeenth century Boerhaave (a pupil of Pitcairn, of Edinburgh) taught clinically and with great *eclât* at Leyden; and to Dr. John Rutherford and De Haen, his pupils, the Edinburgh and Vienna schools owe the introduction of the teaching of practical medicine. In 1754 the celebrated Van Swieten was ordered by Maria Theresa to establish a clinical school at Vienna, and De Haen became the first professor. At the period I speak of it was in Italy and France that surgery chiefly progressed; but Wiseman in England, and Purmann in Germany, gathered, in the bloody tumults of the time, many important surgical axioms.

The Royal Academy of Surgery, founded by Louis XIV., gave a great impetus to surgery; and in the Institution of the Garden of Plants, Dionis found a field for his great talents. He began clinical teaching in France; and after him Saviard, Mareschal, and others pursued it at the Hôtel Dieu. The College of Saint-Côme and the Royal Academy of Surgery gave a life—though often a very stormy one—to surgical discussion and research. Ledran, Louis, Garengeot, and, before all others, J. L. Petit, gave a prominence to French surgery at the beginning of the eighteenth century, which was increased and extended by their successors Desault, Sebatier, Chopart, Anel, Pouteau; and after them in succession Bichât, Dupuytren, Boyer, Roux, and Nélaton, all of whom have been the chief surgical teachers of Europe. It is, perhaps, Desault's chief glory that he established permanently clinical teaching in Paris (in 1750), and to his clinic Chopart, Bichât, Dupuytren, and Boyer in succession followed.

The Edinburgh Infirmary was established in 1736, and in 1748 Rutherford was busy teaching clinical medicine. I have seen it stated that before that date Monro had undertaken clinical surgery, but I have been unable to verify this. Rutherford tells us his plan was—(1) to give a history of the disease in general; (2) then to inquire into its cause; (3) next to give his prognosis; and (4) lastly to lay down indications for cure. In the hands of Cullen (who succeeded Rutherford), and afterwards from Gregory and Alison, clinical medicine in Edinburgh secured a high reputation; while at the end of last century Mr. Russell was appointed Professor of Clinical Surgery, though the anomalous position in which he was placed as regards hospital wards made it impossible for him to succeed. Mr. Russell had no patients assigned him for the illustration of his course, but, on obtaining the permission of the Professor of Anatomy and Surgery (then conjoined), he was allowed to comment upon the cases under the treatment of his colleagues; but he could at any time be debarred by them from access to the wards. When anatomy and surgery were disjoined, the right to teach clinically was by an error attached to the former chair, and thus an opportunity was afforded for the establishment on a truer basis of that department of instruction which has been so ably developed by its more recent incumbents. The exclusive rights now attached to the clinical chair of surgery in Edinburgh have, as is well known, occasioned much heartburning in that school. Nowhere else are students compelled to attend the teaching of one professor. To get this arrangement abolished has been strenuously but futilely tried by the Royal College of Surgeons. So long as the chair is filled by an eminent man, perhaps no harm is done; but such exclusive privileges might be productive of the greatest harm under other circumstances.

In 1782 Richter began at Göttengen the first of those admirable cliniques which have made many of the German schools famous; and now at nearly all the medical centres there exists a most elaborate system of bedside teaching.

In 1792 Sir Astley Cooper began to employ his hospital cases to illustrate his surgical lectures. The effect of this, he tells us, was most gratifying. While in 1791 his class only numbered seventy-three, the year he made this change it increased to one hundred, and the steady augmentation to four hundred and six in 1824 he ascribes to this clinical method of instruction. In 1792 some arrangements for teaching clinical medicine appear to have existed at the London Hospital. In 1813 Sir Benj. Brodie began to give regular bedside lessons.

In Dublin, wards were set aside for clinical purposes as early as 1785, and by degrees a practical school of great eminence arose; for while Crampton, Smyly, and Porter taught clinical surgery, Marsh, Corrigan, Graves, and Stokes brought practical medicine to great distinction.

In our own city clinical teaching appears to have existed as early as 1787, as a ticket for a course of "Lectures on the Cases of Patients in the Town's Hospital, Clyde-street, by Robert Cleghorn, M.D.," is in the possession of my colleague, Professor Cowan. The Royal Infirmary was established in 1793, and shortly afterwards bedside teaching was to some extent pursued, but it was not till 1829 that such instruction obtained a permanent or important place in the instruction of students. No proper or efficient system of teaching could be pursued by the general practitioners of that day, who were elected to serve in the hospital for two years at a time, and who were only in actual charge of patients for three months in each year. In later times, in the hands of Macfarlane, Lawrie, Andrew Buchanan, Moses Buchanan, Lyon, and Fleming, clinical surgery in Glasgow was more carefully cultivated. The teaching has always been quite open, and at no time has this been the case more than at present, when every surgeon in charge of wards in either hospital is placed, as regards the recognition of his teaching, on precisely the same footing, and students are at perfect liberty to choose any of them as their instructor. In order to fulfil the necessary course, each student attaches himself to two teachers, and he is compelled to divide his time between them, attending the "lecture" of both every week, but confining his visits to the wards of one for three months at a time. He has thus the opportunity, during the six months' session, of watching the practice of two men, and yet following to a termination the cases treated.

Before the clinical teaching was transferred from the Royal Infirmary, Professor Gairdner and myself were the only representatives of the University engaged in clinical teaching. When this institution was opened last year, two of our former associates as clinical teachers in the Royal Infirmary joined us here, and to them the University gave the well-earned status of professors. In this way Drs. McCall Anderson and George Buchanan were associated with Dr. Gairdner and myself in this very important and laborious work; but their appointment and official position as Professors of Clinical Medicine and Surgery has in no sense changed the relation in which Dr. Gairdner and myself stand to the teaching, nor has their appointment in any way narrowed or restricted the choice which you are allowed to make of your teachers. These appointments have brought augmented force to our school, but they have conferred no exclusive position on their holders such as was pointed out existed elsewhere.

The conditions favourable to the healthy development of clinical teaching have greatly improved of late years in our school. The division which now so markedly exists between medical and surgical practice, and the restriction to consultation work which several of the teachers have imposed on themselves, have allowed more time to be devoted to hospital duties, and has enabled them to concentrate their attention on special departments; and to this circumstance more than any other do I ascribe that increased vigour which has marked the teaching of later years, and the rapid increase of our school which has followed. The prolonged hospital appointments permit such improvements to be made in practical teaching as were before impossible, and to no event of my professional life do I look back with more satisfaction than the part I took in that reform. The almost complete severance which existed between the University and the hospital up to a few years ago was a total bar to the development of the clinical teaching.

Gentlemen, in closing these remarks I would only add that the duty demanded of us teachers is most anxious and responsible, whether viewed with reference to you or the patients. It is a very grave affair to be charged with the instruction of others in any matter; how infinitely more serious is it when the issues are so momentous and far-reaching as those embraced in medical education! We are entrusted with the practical education of men who go to all quarters of the earth wherever the British name has penetrated. Your knowledge and skill may affect the health and happiness of innumerable families, and any error you imbibe here may be multiplied in endless ways. Yet, on the other hand, all good and true lessons will have a wide circuit for their action, so that the clinical teacher is, as it were, the centre from which far-reaching waves of good and evil may spread. It is also a most anxious duty we have to perform, as we have, as it were, to think aloud before an intelligent audience, and to recognise disease, foreshadow results, and direct treatment almost on the spur of the moment. If this is most trying to a teacher's reputation, there is at least a compensating gain both to himself and his patients, as it must needs render him careful in his words and actions, and in this augmented attention and caution the patients secure a further guarantee for their prudent treatment. All of us, whatever our experience may be, are too likely to err and fail, but if each strenuously endeavours to do his best, he has a right to rely on the loyal support of every true student.

CASE OF NYSTAGMUS OCCURRING IN A COAL-MINER, ASSOCIATED WITH PALPITATION AND PROFUSE SWEATING.

By BYROM BRAMWELL, M.B.,
PHYSICIAN AND PATHOLOGIST TO THE NEWCASTLE-ON-TYNE INFIRMARY.

THOMAS L——, aged thirty-eight, a pitman, married, was admitted to the Newcastle-upon-Tyne Infirmary on the 10th of June, 1875, complaining of dimness of sight, palpitation, and debility.

Previous history. — He has worked as a coal-miner for twenty years, and has been particularly healthy. Has never had syphilis nor rheumatism. For the last four years he has suffered occasionally from palpitation. Eighteen months ago he first felt his sight dim, and noticed when he looked at an object intently that it seemed to move quickly backwards and forwards. The palpitation and dimness of sight have been worse since March, and since this date he has felt short of breath on exertion. He thinks the dimness of sight was brought on by the glare of the lamp which miners use. The pitmen, he says, often complain that the light hurts their eyes; he never, however, knew anyone affected in the same manner as himself.

The family history is unimportant.

Present condition. — He is a pale man, tolerably well nourished, but not muscular. The pupils are equal, contracted, and sensible to light. When he fixes the eyes on an object, the eyeballs oscillate quickly backwards and forwards with a slight rotatory movement. The oscillation is greatest when he looks upwards or to the right. It is also increased by looking at distant objects. It is not increased by a dim light, and is not worse when he assumes a stooping position. He states that the nystagmus is worse since he left off work. When at work he used to look chiefly downwards and to the left. On ophthalmoscopic examination the fundus is seen to be normal.

The thorax is well formed. On palpation a very marked systolic thrill is felt in the first and second left interspaces, just outside the sternum. The percussion note is impaired over the same area, the dulness being best marked between the second and third left costal cartilages. On auscultation a loud systolic murmur is audible over the area of thrill. Its point of maximum intensity is at the middle of the sternum, on a level with the third costal cartilage; from this point it is propagated upwards over the area of thrill to the left sterno-clavicular articulation. The murmur is unaccompanied by a second sound. At the second right costal cartilage and over the course of the aorta, the murmur is heard, but much less loudly. There is no venous hum in the neck. Pulsation and thrill can be faintly felt when the finger is placed deeply in the suprasternal notch. The murmur is just audible in the left suprascapular region. The radial pulse numbers 72; it is equal in the two wrists, full and regular. There are no pressure signs. Every three or four days, sometimes more frequently, the patient is attacked with violent palpitation; the attacks last from a few minutes to half an hour; they occur at all times of the day, and without any apparent cause. The slightest exertion causes profuse sweating. The sweating sometimes comes on when he is at rest, and always follows the attacks of palpitation. The appetite is fair; tongue clean. The temperature in the axilla is 97° F. The other systems and organs are normal. There is no enlargement of the thyroid.

Five minims of tincture of digitalis and ten minims of the tincture of the muriate of iron were ordered three times a day.

June 21st.—Since patient's admission it has been noted that the pupils are frequently unequal, the right being sometimes smaller, sometimes larger than the left. The sweating is sometimes confined to the left side of the face. The temperature on both sides is the same. His general condition is unchanged.

July 3rd.—An attack of palpitation came on to-day in my presence. It commenced at 12.30. The eyes became slightly prominent; the pupils considerably dilated; the cardiac pulsations numbered 144 in the minute. The face was slightly livid; the extremities cold. The patient stated that the attack was a very slight one. At 12.35 he said he would try and "put it away." He took two deep breaths and said, "It is away." At the same moment the pulse fell from 150 to 60 in the minute. Slight pain over the front of the chest was complained of while the palpitation lasted. The patient says when it goes away he feels the heart give a sudden jump, and the pulsation immediately ceases. He can always "put it away" by taking one or more deep inspirations. Sometimes the attack continues for half an hour before it is stopped. The digitalis and iron to be discontinued. To take two minims of liquor arsenicalis thrice a day.

15th.—Was made an out-patient to-day as he had to go home to attend upon his wife who is ill. The liquor arsenicalis has produced no effect, although the dose has been increased. To discontinue it, and to take half a drachm of the liquor ergoti instead.

Aug. 26th.—Was readmitted, as he has been much worse of late. The palpitation and sweating have been most intense; the oscillation of the eyeballs is less; he can now look steadily forwards, downwards, and to the left; when he looks upwards, or to the right, it always commences; when the eyes are at rest, vision is good; his physical condition is otherwise the same. To take one-eightieth of a grain of sulphate of atropia three times a day, and twenty grains of bromide of potassium every six hours.

Sept. 10th.—A violent attack of palpitation came on at 11.10 to-day; the cardiac pulsations numbered 174; the murmur was inaudible, its place being taken by a short rapid pulsation; the radial pulse was small and thready; the extremities cold; the eyes were prominent and staring, the pupils dilated; the respirations numbered 28. He made several attempts to "put it away," but did not succeed till 11.20. He then said "It is away." The pulse at the same moment became full and steady (72 in the minute); the murmur at the same time became loudly audible; no irregularity nor intermittency was observed before the fall. To take half a drachm of the bromide three times a day.

25th.—Says he feels a good deal better; the attacks of palpitation are less frequent and less severe; he has gained four pounds in weight since his readmission; he feels weak and shaky about the legs, but otherwise well; the sweatings are much less profuse. To inhale nitrite of amyl during the paroxysms.

Oct. 1st.—The patient went out to-day greatly improved. The nitrite of amyl completely controls the paroxysms. He said on his discharge, "I wish I had had that medicine sooner."

Remarks.—In THE LANCET of June 12th, Dr. C. Bell Taylor, of Nottingham, reported several cases of nystagmus occurring in coal-miners, and stated his belief that the oscillation of the eyeballs was in these cases a sort of chorea, brought on by strained efforts of vision in an imperfect light. This case agrees with those reported by Dr. Taylor, in so far as the patient is a miner and that he suffers from nystagmus. It differs, however, in the following essential points:—1st. The nystagmus is associated with other symptoms—viz., palpitation, loud systolic murmur, and profuse sweatings. 2nd. The oscillation of the eyeballs is not increased by an imperfect light, nor when the patient stoops. 3rd. It is worse when he looks at distant objects, and when he looks upwards or to the right. 4th. It is not easily curable; for it still continues, although he has been off work for seven months.

We know so little as to the cause of nystagmus that it is impossible to say whether the oscillation of the eyeballs, the palpitation, and the other symptoms of this case were associated as a mere coincidence or not. I am inclined to think their relation was not merely accidental.

In some particulars the case resembles exophthalmic goitre—a disease in which there is good reason for believing the cervical sympathetic to be at fault. Certain facts in this case point in the same direction, and show that the palpitation was due to stimulation of the accelerators of the heart, and not to suspension of the inhibitory functions of the vagus. These facts are—1st. The variable state of the pupils, the right being sometimes larger sometimes smaller than the left. 2nd. The profuse sweatings, sometimes unilateral. 3rd. The condition of the patient during the attacks of palpitation—notably the prominence of the eyeballs, dilatation of the pupil, and coldness of the extremities. 4th. The marked benefit which resulted from the use of nitrite of amyl—a drug which acts by dilating the vascular system.

It is a remarkable fact that the patient was able to "put away the beating" by taking a few deep breaths. This was no doubt due to réflex stimulation of the vagus. Here again is another fact in support of the theory that the palpitation was due to stimulation of the accelerators, for it is unlikely that the vagus would be so readily aroused if its inhibitory functions were suspended.

The instantaneous manner in which the attacks of palpitation ceased is worthy of note. The pulse, from being 174, thready, and almost imperceptible, became *all at once* full, regular, and of normal frequency. There was no stoppage for several beats, no irregularity before the fall took place—facts which were observed by Dr. Farquharson in his lately published "Case of unusually Rapid Action of the Heart."

The characters of the murmur were peculiar. At first I was of opinion that it was hæmic, and in the pulmonary artery. Against this view were the dulness on percussion, the very marked character of the thrill, and the absence of venous hum. I am now inclined to think that the murmur was due either to organic disease of the pulmonary artery or more probably to some congenital malformation.

CLINICAL ESSAYS.

By T. PRIDGIN TEALE, M.A., F.R.C.S.,

SURGEON TO THE GENERAL INFIRMARY AT LEEDS.

No. VI.—ON THE TREATMENT OF VESICAL IRRITABILITY AND INCONTINENCE OF URINE IN THE FEMALE BY DILATATION OF THE NECK OF THE BLADDER.*

THE discussion at the late meeting of the British Medical Association at Edinburgh on Dr. Duncan's paper "On the Examination of the Female Bladder by Dilatation," and his testimony to the benefit resulting from the proceeding, and the extract from the *New York Medical Record*, Aug. 14th, 1875, "On the Cure of Cystitis by Dilatation of the Neck of the Bladder,"—warn me that it is time that I brought before the profession the observations I have made on the subject of this essay during the last eight years. The substance of the essay was read before the Leeds Medical Club in November, 1870, before the West Riding Medico-Chirurgical Society at Leeds in February, 1873, and before the Yorkshire Branch of the British Medical Association at a meeting at Scarborough in November, 1874.

---

* Read before the West Riding Medico-Chirurgical Society at Leeds, February, 1873.

About eight years ago the following case, of which unfortunately I cannot find any record, was under my care at the Leeds Infirmary:—A healthy-looking middle-aged woman had been for some time under treatment for great irritation of the bladder, accompanied with the passage of mucus tinged with blood. Having failed to relieve her by the usual means, I decided to dilate the urethra in order that I might introduce the forefinger into the bladder, and search for some explanation of the pain and bloody discharge, such as an ulcer or villous growth. No definite lesion was discovered; but, to my surprise, in the course of a few days, I found that she was completely relieved. She left the hospital, and I have not heard of her since.

This case struck me forcibly as parallel with the immediate relief which generally follows forcible dilatation of the anus for fissure and spasm of the sphincter; and I determined to profit by the hint. The result is, that during the last eight years the operation of dilating the neck of the female bladder as a means of cure of a distressing and unmanageable malady has been adopted in thirty or forty cases by myself and my friends.

In bringing the subject forwards I am met by three difficulties: the first, that I am proposing to treat *a symptom*, "irritability of the bladder," associated with a great variety of causes, and that, in applying a remedial operation, but little cognisance is taken of the cause of the symptom; the second is a consequence of the first, that the operation does not succeed in every case, and sometimes fails entirely; the third difficulty is this, that I have not yet been able to establish any rule to guide us to the selection of the exact cases to which the operation is suitable. My justification, however, for proposing the operation in the face of such difficulties lies in the fact that it deals with cases which defy all other known methods of relief, which cause intense, prolonged, and often permanent suffering to the patient, and constant disappointment to the medical attendant, and that in a fair proportion of the cases, *perhaps in one third*, absolute cure has been obtained, not in my hands alone, but in the hands of many of my medical brethren who have adopted the operation. It is a sense of these difficulties, the not infrequent failure of the operation, and my own inability to define exactly the cases in which success is probable, which has made me hesitate hitherto to bring the subject before the profession.

A.—Cases in which the Operation may be performed.

The *cases* calling for the operation are those in which there has existed for some months pain at the neck of the bladder and too great frequency of micturition, with or without pus, mucus, or blood in the urine; or incontinence of urine, with a full bladder unable to empty itself completely, or with a nearly empty bladder which is intolerant of the presence of urine. The *time* for doing the operation is when all ordinary means of relief have been tried in vain, whether general or specially directed to the bladder, uterus, rectum, or kidney.

This definition may be said to embrace a very wide range of disorders, having in common the one symptom—irritability of the neck of the bladder. The fact is, the operation has been tried and has succeeded in a great variety of cases. In some successful ones there have been pain and excessive frequency of micturition, giving rise to a suspicion of stone in the bladder, with urine perfectly healthy, and in which, at the time of the operation, the finger failed to detect any fault in the mucous lining of the bladder. In other cases the urine has contained altered pus and mucus and blood, such as is usual where there is vesical calculus, and yet the operation has cured. In others, again, there has been an abundance of unaltered pus, settling in large quantities to the bottom of the vessel, which was afterwards proved to have been derived from a suppurating kidney or other extravesical source; and even in these the operation has given substantial though perhaps temporary relief. More than one case has proved this fact—*that pus from a source external to the bladder may give rise to distressing irritability of the bladder, with pain and excessive frequency of micturition, the bladder itself being apparently sound;* and that the vesical irritability may be cured—for a time, at any rate—by dilatation of the neck of the bladder, although the original cause of the irritability remains in force.

Vesical incontinence.—In two cases (Mr. Scattergood's and Mr. Horsfall's) a perfect cure, and in one of my own cases very great mitigation, of vesical incontinence has resulted from dilatation. In these cases I suspect that there is an over-sensitive state of the mucous membrane at the neck of the bladder, which, the moment an attempt is made to empty the bladder, sets up spasm of the vesical sphincter, and arrests the act of micturition after the escape of a very small quantity of urine, the bladder remaining nearly full and ready in a very few minutes to induce another painful and equally ineffectual attempt at micturition. Thus an overflow of a bladder disabled from correct micturition by irritability of its sphincter becomes an incontinence. Thus also the operation I have proposed by rendering the irritable sphincter vesicæ powerless for spasm, perhaps temporarily incompetent, allows the bladder to empty itself completely, and the cervical mucous membrane to recover its tone.

B.—Operation.

The patient being under the influence of an anæsthetic, Weiss's dilator is introduced into the urethra and dilatation continued until the urethra is distended so as to admit two fingers. The dilator ought to be passed as far into the bladder as possible, otherwise the branches of the instrument yield too much to the resisting neck of the bladder. It is desirable to dilate slowly, so as to avoid, *as far as possible*, laceration of the mucous membrane of the urethra. In many cases this laceration occurs, although due care has been taken, and much more after-pain results in consequence during the first day or two.

Sometimes instead of Weiss's dilator I have used the conical probe-gorget, designed by my father for median lithotomy, as a guide for the finger, by which the remainder of the dilatation is effected. On the withdrawal of the dilator it is generally found that the urethra still grasps the finger. The dilatation thus attained enables the surgeon to explore the interior of the bladder. Generally the bladder has appeared to be perfectly healthy, being soft and velvety to the touch throughout. Occasionally portions have been raised and indurated, as if ulcerated, but I have thought this sensation might be deceptive, and produced by the corrugations of an empty bladder. I cannot say that I have undoubtedly detected ulceration by the finger in any of these cases. In two or three instances it has turned out that the bladder was permanently contracted to a cavity little larger than a thimble.

C.—Objections to the Operation.

(1) *Fatality.*—In three instances death has occurred within a short time of the operation. The first was a patient of my own and of Mr. Hodgson Wright of Halifax, who was excessively worn down by the sufferings of several years. The operation gave her much relief from pain, and was a great comfort to her, but her failure of health was progressive, and she died in about five weeks. At the autopsy it was discovered that the bladder was healthy, but that the pus in the urine came from the kidney. The second, a case of Mr. Wheelhouse's, was a child about four years of age, who had been relieved a year before by this operation, Mr. Wheelhouse having introduced the finger into the bladder for the purpose of exploration, and having thereby arrested the symptoms from which the child was suffering. A year later the child returned to the hospital with a relapse of the vesical symptoms. The operation was repeated, this time as a means of cure, not of diagnosis, and the child died in a day or two. At the post-mortem it was found that the bladder was healthy, and that the pus causing the symptoms came from a diseased kidney. The third fatal case was under Mr. Jessop. A young woman, worn down by vesical trouble and incontinence of urine that had existed since childhood, was submitted to the operation. The introduction of the finger found the bladder contracted to the size of a large thimble. She died in the course of a few days, and at the post-mortem strumous degeneration and suppuration of the kidney was found. I think I have heard of another fatal case, but I am not certain.

It may be said that these fatalities are an argument against the operation. To me they seem to be the reverse—

a reason why cases of this class ought not to be allowed to drift year after year into this broken-down condition, in which a comparatively trivial operation can extinguish the feebly sustained vitality. It rather raises the question suggested by Mr. Charles Smith, of Halifax, whether the disease of the kidney may not have been induced by the prolonged vesical irritation.

(2) Another objection may appear in the possibility that *the source of the irritation may not be in the bladder itself,* but may be pus entering the bladder from the kidney or some other extraneous source. The fatal cases of my own, and of Mr. Wheelhouse, already referred to, prove that the discomforts of the irritability of the neck of the bladder may be suspended or relieved by the operation, although the irritability may have originated in a cause external to the bladder.

(3) A third objection may be raised in the *danger of producing incontinence of urine.* My first idea about the operation was, that by producing *temporary incontinence of urine* we might so set at rest the vesical structures that any ulcerated or abraded surface might heal, that morbidly irritable or hypertrophied sphincter-fibres might lose their excessive irritability, and that any unhealthy condition of urine resulting from an imperfectly emptied bladder (as occurs in the male from enlarged prostate) might, by its freedom of escape, regain its normal character. This was my original idea—namely, to producd incontinence. And I was induced to believe that any incontinence would be temporary by what I had seen of the removal of large-sized calculi in the female with rapid recovery of vesical competency. It has happened, however, that the operation was rarely followed by any incontinence of urine, and many of the most rapid and most complete cases had not even temporary incontinence. On the contrary, instead of relieving the bladder every few minutes or every hour, they were able to retain their urine the greater part of the night immediately following the operation. Other cases, again, had incontinence of urine for a few weeks. One case for a few months had very little power of retaining urine and then recovered completely, the pain and irritability having been relieved from the first. Two cases that I know of have suffered from permanent incontinence of urine. It does not, however, appear that the liability to permanent incontinence depended upon the degree to which the dilatation was carried.

(4) *Relapses.*—In Mr. Wheelhouse's case the cause of relapse—suppuration of the kidney—was revealed by the post-mortem. In one of my own cases the operation of dilatation had been performed by Dr. Bell, of Bradford, to the extent recommended in my paper read at Leeds, but without relief. A few months after Dr. Bell and I dilated again more freely to the extent that would admit three fingers. After some days of incontinence she recovered power over the bladder. From passing urine every ten minutes or a quarter of an hour with groans, she was able to relieve herself without pain, and though not cured, she is only disturbed five or six times each night. In two other cases the operation was repeated, and I believe both are comparatively well, having occasionally slight attacks of pain, with increased frequency in micturition. This, however, may be said, *that a relapse* or *the failure of a first operation ought not to deter us from giving a second trial.*

D.—Literature.

I have failed hitherto to find any authors who have proposed this or any similar treatment for affections of the female bladder. The nearest approach to it is the proposal of Sir James Simpson (mentioned shortly after his death by Mr. Lawson Tait) to cure irritable ulcer of the bladder—in other words, severe vesical irritation—in the female, by establishing a temporary vesico-vaginal fistula. His object was to obtain, what I aimed at by dilatation—physiological rest for the distressed organ. In works on female diseases the treatment of this distressing condition is generally dismissed in a few words. From the article referred to at the beginning of this paper it is clear that the Americans are at work in the same direction, and the case quoted is a strong confirmation of the correctness of the principle of treatment here advocated.

No less a confirmation is the advocacy of Dr. Duncan of dilatation of the neck of the female bladder as a means of exploration, and the testimony of his patient to the direct benefit derived from it. Further confirmation of this principle may be drawn from the fact that Mr. Syme treated somewhat similar cases in the male by incising the neck of the bladder as if for lithotomy, and from the rapidity with which the inflammation of the bladder produced by a calculus subsides under the free drainage established by lateral lithotomy.

(To be continued.)

CASE OF

CONGENITAL HARD CANCER OF THE LEG IN AN INFANT;

AMPUTATION DURING THE FOURTH MONTH; RECOVERY AND PERMANENT CURE.

By KELBURNE KING, F.R.C.S,
SURGEON TO THE HULL GENERAL INFIRMARY.

On the 28th of March, 1871, I was consulted regarding a male infant about two months old under the following circumstances. At its birth, on Jan. 31st, 1871, Dr. Robert Savile, who attended its mother in her confinement, observed a tumour on the outer side of the right ankle, about the size of a filbert. It was not painful, nor did it seem to cause any inconvenience, but it gradually increased in size. When I saw it it was about as large as a walnut, was closely connected with the lower end of the fibula, from which it seemed to spring. The skin covering it was quite healthy, having no appearance of vascular excitement. The tumour was gradually lost in the surrounding healthy parts, from which it was not separated by any distinct boundary. By its size and pressure the foot was forced inwards, and the tumour occupied to some extent the position of the foot. It was hard to the touch and adherent to the skin, which was incorporated in the firm fibrous mass of which the tumour seemed to consist. It was firmly fixed, and could not be detached from the surrounding parts. There was no feeling of softness or of elasticity; it was throughout firmer and harder than any natural tissue except cartilage and bone. The child was thin and delicate-looking.

Although hard cancer is exceedingly rare in infants—in a tolerably extensive surgical experience I have never seen it before,—I concluded from these physical signs that there was no doubt—firstly, of the malignant nature of the tumour; secondly, of the necessity of its removal; and thirdly, of the impracticability of removing it by itself so as to save the limb. Accordingly, but very reluctantly, I gave it as my opinion that no proceeding short of amputation of the leg would meet the circumstances of the case; and, as the child had an anæmic appearance, I did not press this extreme measure, and felt rather relieved to hear in a few days from Dr. Savile that the parents declined to submit their child to the chances of an operation.

In the first week of May I heard again from Dr. Savile that the child had passed safely through an attack of whooping-cough, that its health was improved, but that the tumour was becoming larger, and the parents were anxious to have something done for it. I saw it again on May 10th, and was much struck by the change in the child's appearance. He had grown much, was fat and well nourished. But the tumour had doubled in size; the skin over a portion of its surface had ulcerated within the last few days, and there was a discharge of serous fluid mixed with blood. Under these circumstances I had no hesitation in recommending immediate amputation.

With Dr. Savile's kind and able assistance the following operation was performed:—The knife was entered just over the head of the fibula, and a semilunar incision was made through the skin over the front of the leg. A similar incision was made on the posterior aspect, the knife was passed into the tibio-fibular articulation, so that the whole of the fibula was removed, and then the tibia was sawn across a little below its anterior spine. The popliteal artery was divided before its bifurcation, a ligature was placed upon this vessel and two small arteries, and the operation—performed under the influence of chloroform—was completed without the loss of one teaspoonful of blood.

Dr. Savile, who from that time took charge of the case, informed me that the sutures were all removed by the 19th of May; the ligatures came away on the 22nd, and the stump was almost healed on the 26th, at which date the child was in vigorous health.

I happened to be consulted the other day by a patient who lives close to this child's parents, and who told me that the boy has had no return of disease, but is a remarkably fine healthy little fellow, and hops about most actively on his one leg.

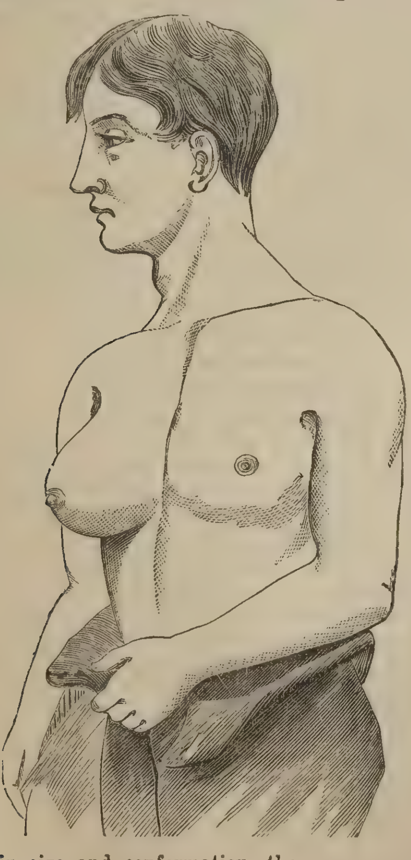
On microscopical examination the tumour was found to consist of a mass of caudate cells of rather small size and possessing but one nucleus. Histologists might refuse to call it by the name of cancer. But it was harder than any structure of the healthy body except bone and cartilage; it grew rapidly, encroaching on and displacing the normal parts; and it finally ulcerated and discharged bloody fluid. It possessed, therefore, all the usual physical signs of hard cancer of the most malignant kind, and would doubtless have soon led to the death of the patient.

Hull.

CASE OF ABNORMAL DEVELOPMENT OF THE RIGHT BREAST IN A SEAMAN AT THE AGE OF PUBERTY.

BY DEPUTY INSPECTOR-GENERAL MORGAN, C.B.,
ROYAL NAVAL HOSPITAL, HONG-KONG.

(*Communicated by the* DIRECTOR-GENERAL OF THE MEDICAL DEPARTMENT OF THE NAVY.)



A. B., aged twenty-one, ordinary seaman, was admitted into the Royal Naval Hospital, Hong-Kong, on May 14th, 1875, with what was said to be a chronic enlargement of the right breast. On examination, the right mamma presented, in size and conformation, the appearance of the well-developed breast of a full-grown woman, lobulated, with an enlarged brown-coloured areola. The nipple, however, corresponded in size with that of the left breast. The man states that he first observed the right breast to be larger than the left about the age of sixteen and a half years. Since that time it gradually increased in size until it attained its present dimensions. There has been no kind of secrĕtion from the nipple at any time. He has not experienced any pain or uneasiness in the breast except, when drilling aloft, it has come in contact with ropes, and necessitated his presenting himself as a candidate for the sick-list with a slight contusion. The genital organs are fully and well developed.

The accompanying drawing, for which I am indebted to Staff-surgeon Siccama, of H.M.S. *Modeste*, is a very accurate and faithful representation of the case.

UNIVERSITY COLLEGE HOSPITAL.

TWO CASES OF COMPOUND FRACTURE OF THE LOWER END OF THE HUMERUS.

(Under the care of Mr. CHRISTOPHER HEATH.)

THE following cases of serious injury to the elbow-joint are favourable for comparison, since the accidents occurred within a few hours of each other, and the patients lay side by side under precisely similar circumstances, and were treated in the same way, but with very different results. The first case appeared to be the more serious at first, both on account of the extent of injury and the age of the patient, yet he recovered without having any bad symptoms after the first few days. The second case ended in excision, from which the patient recovered. It is difficult to suppose that any better result could have followed the use of "antiseptic treatment" in the first case than occurred under the old-fashioned plan of applying a piece of lint dipped in blood; and the disorganisation of the joint in the second case seems to have been set up by a loose fragment of bone which no external treatment could have reached. The question of primary excision must necessarily arise in cases of injury to the elbow-joint, and where the amount of damage is great there can be little doubt of its advisability; but where the injury is confined, as in this case, to a single bone, with no positive proof of the joint being involved, most surgeons would agree in waiting for more precise indications before submitting the patient to a serious operation.

For the following notes we are indebted to Mr. A. P. Gould.

On June 22nd, W. M——, aged fifty-two, was knocked down by a cab, the wheels of which passed over his right elbow. He was at once taken to the hospital. On examination, he was found to have a transverse fracture of the shaft of the humerus close to the lower end, and the lower fragment was evidently split, as the inner condyle could be moved apart from the outer, and this produced crepitus. There was a wound, about a quarter of an inch long, just above the inner condyle, leading down to the fracture, evidently produced by the projecting lower end of the shaft; from this there was a free escape of blood. The patient was at once admitted, and the arm was put upon an angular splint; a piece of lint dipped in the blood was applied over the wound, and an ice-bag was applied.

26th.—There is considerable swelling all round the elbow, with a good deal of tension; skin is marked with a slight red flush; not much pain in the part. From this date the redness, swelling, tension, and pain gradually decreased.

28th.—Swelling much less; no pain; suffers from constipation and flatulence, which are treated by the usual means.

30th.—Bowels have been freely open; there is a good deal of bruising all over the back of the elbow; he complains of a little rasping pain in the joint.

July 4th.—Splint changed to-day; a similar one put on. No redness or tension; very little swelling; the wound is now a superficial sore.

17th.—There is swelling and pain in the position of the left external iliac vein, and œdema of the leg and foot. Ordered to have the leg and foot slightly raised, and to take a saline mixture.

20th.—No pain in the groin; swelling and œdema much less.

24th.—Patient left the hospital to-day. It is noted that the wound has quite healed, that the bones have united, but no passive movement has been applied. He is to attend as an out-patient for this purpose. There is still slight œdema of left leg; no pain or swelling in the groin.

On June 23rd, J. A——, aged twenty-two, ostler, was riding on a horse, when he fell heavily on his right elbow. Finding he was severely injured, he came to the hospital, and was admitted at once. The humerus was found to be broken across at the lower end transversely, and the internal condyle was broken off. The forearm and lower fragment were displaced forwards. Over the lower end of the upper fragment was a wound an inch and a half long, through which the bone could be seen. The displacement was easily reduced by extension and manipulation. The patient appeared to be a fairly strong man, but of unsteady habits. The arm was placed on an angular splint, dry lint placed over the wound, and ice-bags applied.

24th.—Temperature 100·2°; pulse 88. Slept well; much less pain.

25th. — Temperature 100·6°; pulse 100. There is a good deal of swelling about the parts, and there is more pain in the joint.

29th. — There is considerable swelling and tension about the joint. On the surface are two or three blebs, which have become purulent. Temperature 100; pulse 88.

July 2nd. — There is great tension, redness, and pain up along the back of the arm; pus can be squeezed out of the wound from as far as four inches above the joint. Temperature 100·2°; pulse 96.

4th.—An incision about an inch long was made vertically up from the wound. About an ounce of pus came away. Dressed with an oakum poultice.

5th. — No bagging of pus, which is escaping freely; less redness.

16th. — Since the 5th inst. the temperature has ranged from 100° to 101°; the patient has evidently been losing ground. To-day it is noted that he is pale, perspires much at night, his pulse is weak, tongue slightly furred, and appetite poor. There is very considerable swelling round the joint, both above and below; suppuration is free, and pus flows from the wound when pressure is made over the outer condyle. He was ordered sulphate of quinine and sulphuric acid, fish, and four ounces of wine.

20th. — Temperature 101°; pulse 106. The granulations at the wound form a fungus, which protrudes an inch above the surface. There is more discharge, and the swelling round the elbow has considerably increased the last two days. Fluctuation is distinct over the front and outer side of the joint.

21st.—This afternoon the patient was placed under the influence of nitrous oxide gas and ether, and, in Mr. Heath's absence, Mr. Erichsen proceeded to excise the elbow-joint by a longitudinal incision, about nine inches long, over the back of the limb. The humerus was first sawn off an inch and a half above the line of fracture, which was an inch above the condyles; but as the anterior part of the bone was bared of periosteum a little higher up, the healthy periosteum was stripped up and another three-quarters of an inch of bone removed. The broken ends of the bone were surrounded by pus, and pus was burrowing up the limb, and had extended all round the elbow-joint as well as inside. The articular cartilages were eroded. The ends of the radius and ulna were then removed in the usual way. The limb was put on an angular splint, and the edges of the wound brought together above and below, a drainage-tube being inserted in the middle. An oakum pad was applied over all. Extending down from the transverse fracture in the humerus was a vertical fissure running into the joint, and separating the two condyles; in addition a small fragment of bone was found lying loose in the cavity bathed in pus.

22nd.—Has passed a good night. Perspires much. Temperature 103°; pulse 124.

23rd.—Temperature 102·4°; pulse 120. The arm is more swollen; there is diffused redness all round the joint. There is some serous discharge from the drainage-tube. He sleeps better; sweats less; appetite good. Wound dressed with carbolic lotion. In the afternoon the sutures were removed, a fresh drainage-tube put in, and the part was irrigated.

24th.—Limb less swollen; redness decidedly less. Temperature 100·2°; pulse 112. Evidently improved.

30th.—The parts have healed except at two points, the original wound and where the drainage-tube is inserted.

August 1st.—Irrigation stopped. Dressed with red wash.

9th.—The general condition of the patient has wonderfully improved; the swelling of the arm has much subsided; there is almost no tenderness and no redness. The forearm is being gradually drawn up nearer to the arm.

17th.—Union is much firmer. Passive motion to be begun. Temperature 98·4°.

31st.—Swelling about joint much less. The muscles of the limb are wasted, especially the deltoid, and this allows the head of the humerus to drop slightly. The length of the arm cannot be accurately determined. There is very free motion between the arm and forearm, the bones of which appear to be about two inches apart. Patient has no power of movement at the elbow; he can move his wrist slightly, and also the thumb and two outer fingers; there is no movement in the ring and little fingers. Sensation is perfect except in little finger and inner side of next digit, where it is imperfect.

Sept. 2nd.—There is considerable swelling, induration, pain, and tenderness about the inner part of the arm. A poultice was ordered.

3rd.—As no relief has been afforded, Mr. Heath enlarged the upper of the two sinuses, and evacuated a quantity of pus, which greatly relieved the patient.

18th.—There are two very small, superficial, granulating, healing wounds over the back of the elbow. There is very free movement in the joint, but no voluntary power. He can now feel almost perfectly in the inner two digits, and can move them a little. The power of movement in the thumb is very free. If the fore and middle fingers are held he cannot move the two others at all. Discharged from the hospital to-day to Eastbourne.

The patient returned from the seaside at the end of a month with the incision of the operation perfectly healed, but with the sinus on the inner side still open. The motion in the elbow is very free; but the patient has as yet but little power in the limb, which is still somewhat swollen.

CASHEL UNION HOSPITAL.

SURGICAL CASES.

(Under the care of Mr. LAFFAN.)

We are indebted for the following notes to Mr. James O'Dwyer:—

Amputation of the Penis for Epithelioma.—In the following case amputation of the penis was performed after the method proposed by Mr. Tyrrell of Dublin, which is as follows:—Before amputating, a strong pin is inserted through the crura of the penis in front of the pubis, and the pin is allowed to remain in that position for several days afterwards. After the organ has been removed, the urethra is slit up for half an inch, and its mucous membrane is stitched to the skin. The advantages claimed for the operation are that it prevents retraction of the stump of the penis, and that it greatly lessens the difficulty of dealing with subsequent hæmorrhage; and, lastly, that there is no liability to consecutive urethral contraction.

T. M——, aged fifty-five, unmarried, a tailor by trade, was admitted on May 17th, 1875. The previous history was as follows:—He stated that he had enjoyed very good health up to September, 1874, when he noticed a little spot and hardness in the region of the glans penis. He also felt a pain in the arch of the foot. This pain, to use his own words, was accustomed to run up to the groin and out along the penis. He denied having had venereal disease, but admitted that he had not been of cleanly habits. He stated he was not a drunkard. On admission, the glands in both inguinal regions were slightly enlarged. He passed a large quantity of water, and had frequent calls to micturate. The penis presented a very ugly appearance, being greatly enlarged, indurated, and ulcerated through in many parts. The case being clearly one of epithelioma in an advanced stage, removal was resolved on. On May 18th the patient was placed under ether, and amputation at the pubic arch was performed. Very little bleeding occurred in this case. The mucous membrane of the urethra and skin united in a few days. No stricture ensued, and he left hospital on June 28th following perfectly well, and continues so up to present date.

Necrosis of Circular Piece of Front of Tibia.—J. H——, aged thirty-two, married, a labourer, came to the hospital on July 20th, 1874, with disease of the leg. The disease, which occupied the diameter of about a crown-piece, and extended half an inch in depth, was caused by a blow of a stick whilst hurling. The man was strong and robust; but as the reparative processes had hitherto been all but stationary, and so much time would be required for the complete throwing off of the dead part, Mr. Laffan deemed it advisable to save time by operative interference (a point of very much consequence to a poor day labourer). He therefore resolved to gouge away the dead bone, which was accordingly done on the 30th August. Antiseptic dressings were employed. The situation of the necrosed bone did not admit of any covering of soft parts being provided from neighbouring tissues. It was interesting to observe how this want was supplied by the perfect coat of granulations thrown out by the cut surface of the bone. Another point of interest was the death of a small rim of periosteum, which was left around the margin of the bony cavity, and the shooting up of granulations by the underlying bone. The cavity left by the removal of the dead mass filled up after a few weeks in a complete manner; and the patient left the hospital well, and continues so up to the present time.

Spermatorrhœa.—Several cases of the above-named affection have presented themselves, and the same difficulties have been encountered in their treatment as have beset most practitioners in dealing with similar cases. The entire success which attended Trousseau's compressor in one of these cases makes it worthy of special mention.

J. R——, aged twenty-eight, a policeman, had suffered for six years from seminal emissions, which were brought on by the usual causes. He had been under treatment a long time, but without benefit. Mr. Laffan, under whose charge he then came, also tried for some weeks various remedies, but with a like unsatisfactory result. He then ordered a compressor, which was to be worn every night. This did its business so admirably that on no night on which it was worn did any discharge whatever occur.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

AT the ordinary meeting of this Society, held on the 23rd inst., Sir James Paget, President, in the chair, an interesting debate took place upon the relation of syphilis to aneurism. In the paper on Aortic Aneurism in the Army, by Mr. F. Welch, it will be seen that the author has arrived at the conclusion that a very large number of cases of this affection result from a specific change in the inner wall of the vessel —a change which is due to the syphilitic virus. The paper, which was full of interesting facts, and embodied the results of most painstaking research, was cordially received, although it will be seen that the majority of the speakers declined to adopt the conclusions of the author.

Previous to the reading of the paper the President announced that Dr. Pavy, having succeeded in obtaining a large quantity of sugar from the urine of healthy persons, had brought some specimens of the sugar to exhibit to the Society.

After a brief communication had been read by the secretary, in which Dr. PAVY pointed out that hitherto the existence of sugar in the urine had been doubted by many physiologists and denied by most, he proceeded to show that the slight and variable reaction obtained on boiling healthy urine with the copper solution was mainly due to the presence of urates. In his experiments he had been careful to take samples of perfectly healthy urine, which had yielded no reaction with copper, and had extracted the sugar by means of acetate of lead. When urine is treated with this salt, the whole of the urates and urea are precipitated. The filtrate is then treated with ammonia, and more of the lead salt added until precipitation ceases. The sugar is carried down in this second precipitate in combination with the lead, from which it can be liberated by oxalic acid or sulphuretted hydrogen. The latter reagent is the best for the purpose, although the process is a tedious one. Dr. Pavy then showed a sample of sugar so obtained, and performed a series of tests upon it—viz., Moore's (liquor potassæ) test, Boettger's (bismuth-reduction) test, the test by reduction of copper (the solution used consisting of sulphate of copper, tartrate of potash, and caustic potash), and lastly the fermentation test. The reactions obtained by all these processes were very marked. Referring to the fermentation test as a crucial one, Dr. Pavy showed the products of fermentation—viz., carbonic acid and alcohol, the former by absorbing the gas in the collecting-tube by means of caustic potash, and the latter by means of bichromate of potash and sulphuric acid. In order to succeed with the fermentation test, it was necessary to neutralise any free acid that might be present in the product obtained from the urine.

The paper of the evening, on "Aortic Aneurism in the Army, and the conditions associated with it," by FRANCIS J. WELCH, F.R.C.S., Assistant Professor of Pathology at the Army Medical School, Netley, was then read. The following is an abstract of the paper:—The object of this paper, in view of the discrepancy of opinion on the causation of aortic aneurism, is to endeavour, by deductions made from a series of post-mortem examinations conducted at the Royal Victoria Hospital, Netley, to place certain features of causation and pathology of this vascular lesion upon a basis of stability. The average death age was thirty-two years; average period of service performed by the soldier twelve years; average duration of the lesion a year and one-twelfth. In five instances the dilatation of the vessel was multiple, the largest number of aneurisms in any one case being four; and in two instances an innominate aneurism was superadded to the aortic sac. The lesions (otherwise than the sac itself) observable in the bodies were capable of being arranged under two heads—(*a*) those mechanically produced by the pulsatile tumour, and (*b*) those indicative of a diathesis or general internal agency, and these latter were rarely otherwise than syphilitic. The main object, however, of the paper being not so much to detail the disease as to inquire into its surroundings and causation, the statistics of its dispersion throughout the service are first given to show that the disease is not peculiar to climate, station, or occupation, nor connected with age or any condition of system brought about by length of service, and upon this negative basis is superadded the positive basis furnished by the morbid anatomy and life history of the cases comprised in this paper, the deductions arrived at being placed in the form of two propositions, the first of which refers to the condition of the vessel, and is as follows:—"That the aneurismal tumours are associated with and preceded by a diseased condition of the contiguous layers of the internal and middle coats of the vessel—a tissue growth terminating in degenerations which, by impairing the elasticity and contractility of the walls, allows of their expansion and dilatation under the tension of normal arterial blood pressure, or this abnormally increased by any cause." The term "atheroma" is regarded as an extremely unsatisfactory designation of the disease, inasmuch as it expresses one possible phase only of it, that of degeneration, and allows of the accumulation under the same nomenclature of structural changes divergent in origin and progress. Two forms of vessel deterioration are embraced by it—the one a distinct tissue-growth, an end-arteritis—an active lesion, having as one of its sequelæ the aneurismal sac; the other, a mere opacity, or occasional fatty degeneration of the inner surface of the vessel—a passive phase, followed apparently by no deleterious results between eighteen and forty years of age, the period of the soldier's service. The pathological chain of continuity between the aortic disease characterised by a tissue-growth and the aneurismal sac is complete and unbroken, and hence the important problem in etiology is to elucidate the exciting agencies in the development of the end-arteritis of the internal and middle coat, and these are given in the second proposition of the paper, which stands as follows:—"That these two forms of textural derangement of the aorta [the two spoken of as included under 'atheroma'] are dissimilar in origin and causation; that the limited passive opacity is connected with long-standing diseases of various kinds inducing a diminished vitality of the system at large; that the structural growth is, in the major number of instances, associated with syphilis, and, in a minor degree, with rheumatism and alcoholism as causations; hence it follows that as the latter phase is the commencement of that pathological sequence of events under one aspect terminating as aneurism, the means for the prevention of the aneurismal tumour must be essentially directed towards the elimination of these special exciting agencies." The 34 cases of aneurism analysed stand as under: 50 per cent. in subjects saturated with the syphilitic virus, and with no other diseased conditions to detract from this deduction; 14 per cent. where syphilis was probably present, but not beyond doubt; 5·8 per cent. in acute rheumatic diathesis; 5·8 per cent. with excessive intemperance; 2·9 per cent. with syphilis, rheumatism, and alcoholism combined; 17·64 per cent. with no known conditions, from absence of information; and 2·9 per cent. where no associated condition could be elucidated. But, as the aneurism is one sequel only of the aortic disease, a table is given to show the associated systemic conditions of the aortic lesion as exemplified in 117 cases as follows:—46·1 per cent. in undoubtedly syphilitic subjects; 6·8 per cent. probably syphilitic, but not beyond doubt; 21·3 per cent. in phthisical subjects; 14·2 per cent. with no records for determination; 5·9 per cent. with heart disease; 5·7 per cent. with various other diseases individually small. This table includes both forms of the aortic disease, the active growth as well as the passive degeneration, but shows a great preponderance with syphilis; the subjoined facts, however, separate the lesions, and place each on its proper basis. In 56 cases of syphilis terminating fatally through special lesions, 60·7 per cent. illustrated aortic nodulation, the major part of a severe type, and in about one-third of these (i.e., 18 out of 56) the vessel disease had led on to dilatation more or less pronounced—that is to say, were in the infantile stage of aneurism, and required only further development to bring them under this classification. Adding these infantile aneurisms, and including one infantile aneurism subsequently mentioned as due to the acute rheumatic diathesis, to the 34 of this paper, we have a sum total of 53, and of these 66 per cent. occurred in subjects infected with syphilis, but with no other diseased conditions to neutralise the deductions arrived at as the point of causation. Again, 106 post-mortems were taken, in which the non-existence of syphilis, both from the life history and after-death data, was fairly deducible, in order to view the subject from an opposite direction, and the following results came out with reference to aneurism and the aortic disease:—Five cases of aneurism were present, and these are included in the aneurismal table of this paper under acute rheumatism, intemperance, and no known cause. Of the aortic disease we get,—in 1 instance it was severe, and had led on to dilatation, in an acute rheumatic diathesis with great intemperance; in 5, or 4·7 per cent., the inner wall of the vessel was corrugated but not dilated; 3 phthisical; 1 alcoholism; 1 aortic valve disease; in 29, or 27·3 per cent., the lesion was to be included under the passive phase of atheroma, mere opacity, and of these 15 were associated with phthisis, and the remainder with renal affections, dysentery, diabetes, scrofula, lupus, cancer, in nearly equal proportions. Hence, then, from whatever light we regard the disease, the same feature becomes apparent, and as these aortic aneurisms are associated with syphilis to the extent at least of 66 per cent., and as nodular disease of the aorta is not often exemplified otherwise than with it, it becomes an incontrovertible deduction that the syphilitic virus must be regarded as a very potent cause in the development of the arterial lesion and its sequel, aneurism; but not the only one, for, as minor agencies, we must include the acute rheumatic poison and alcohol. It is considered that the chest constrictions to which the soldier is liable from the accoutrements, pack, &c., act as fostering influences to the diseased conditions engendered by syphilis, rheumatism, and alcoholism, these probably inducing dilatation in the deteriorated vessel when no such result might ensue under ordinary circumstances and under such amounts of physical exertion as pertain to the civil portion of the community. The summary of the paper is as under. (1) That in the army we have a lesion of the aortic walls characterised by the presence of a fibroid growth mainly in the internal coat, which, as a rule, ultimately disintegrates, and that this growth is connected with syphilis in a major degree, and rheumatism and alcoholism in minor degrees as exciting agencies. (2) That this disease of the aortic coats may retrogress without producing any marked ulterior results upon the system at large, but if extensive or severe, as a rule it is followed by one of three fatal phases—formation of aneurisms, implication of aortic valve, or hypertrophy with or without dilatation of one or more of the heart's cavities. (3) In the army there is also a lesion of the aortic walls characterised by limited opacity or fatty change of the normal textures of the internal coat. This is common to all diseases associated with prolonged general deterioration, and especially lung destruction, but it does not appear *per se* to lead to ulterior results. (4) That the chest constrictions and temporary forced exertions to which the soldier is liable, act as adjuvants to the aortic disease in the production of aneurism, as fostering influences to the germ laid by syphilis, rheumatism, and alcoholism. (5) That in the adoption of preventive measures against aneurism the attention must be primarily directed against the causes of the aortic disease, notably the suppression of syphilis, and secondarily against the conditions of dress &c. which assist in its development.

A vote of thanks having been accorded to the author of the paper, the PRESIDENT pointed out that it raised the whole question of syphilis in relation to aneurisms (other than aortic) in young subjects. The syphilitic origin of aneurism had frequently been mooted, and the opportunity was now afforded for the expression of opinion upon the subject.—Dr. DOUGLAS POWELL, after alluding to the value of the accurate and minute pathological details contained in Mr. Welch's paper, said that the question really was—is the arterial lesion he describes one special to syphilis, or is it similar to, or identical with, that found in non-syphilitic subjects? On this point there was great discrepancy between the cases of aneurism occurring in civil and those in military life. He confessed that he had only met with one case in which it could be said with certainty at the post-mortem examination that the lesion in the aorta was syphilitic. There was here the same nodulation and depressions of the inner coat as described by Mr. Welch—not, however, limited to the aorta, but affecting also the pulmonary artery. It was, indeed, the occurrence of this lesion in these two sites that rendered the view as to their syphilitic origin a feasible one. He did not believe that the lesions described in the aorta alone could be held to be distinctive of syphilis, and he could not help thinking that army surgeons had been led to exaggerate the relationship existing between syphilis and disease of the great vessels. Disease of the heart is much more common in military life than in the civil community, and yet syphilitic disease of the heart is notoriously rare. It did not appear that any of the author's cases of men "saturated with syphilis" had shown syphilitic affection of the heart, and he thought this should be taken into consideration before referring the lesions in the aorta to that disease. In round numbers, out of 500 soldiers discharged from the service or dying daily, 450 had heart disease, and the remaining 50 syphilis. Then had not the author been a little biased by the life history of his cases? The number of cases returned as syphilis in the Army Returns was very great, and it was a question whether in many cases the slightest venereal excoriation had not led to the case being recorded as one of syphilis. It was impossible that any case of venereal disease should escape being recorded since the men were periodically examined; and he (Dr. Powell) believed that many men had syphilis written against them who were not syphilitic, whereas many who (medically speaking) were intemperate had not been returned as such. In the Indian Army Reports the number of cases returned under the head of "constitutional syphilis" exceeded the total number returned under the head of local disease of the generative and urinary organs; and it was significant that of these cases of "syphilis" only about one in three exhibited secondary symptoms. He thought, then, the value of the evidence deduced by the author from the life history of his cases to be much weakened, owing to the inaccuracy of the record.—Mr. Brudenell Carter was desirous of a more precise definition of the word "syphilis," as employed by the author of the paper. Was the patient to be regarded as syphilitic in whom in previous years there had been slight syphilitic manifestations which had never further developed? He had lately seen a patient who died from aneurism, who in 1859 had exhibited a slight syphilitic rash, but who had been free from any manifestation of the disease from that date to the time of his death. What was the definition of syphilis in the public service? Out of 1000 volunteers for the Arctic expedition, only 9 were accepted, all the remainder being rejected as being the subjects of syphilis! If the same criteria existed in the other branch of the medical service as in the navy, not much value could be placed upon the statement that the patient had had syphilis.—Mr. Myers said that he had arrived at totally opposite conclusions to the author of the paper. In the first place, the statistics of Mr. Welch were quite different from those of Professor Maclean, whose report showed that syphilis could *not* be regarded as a cause of aneurism, for in that report, out of 51 cases, only 6 were due to syphilis. Surely if there were a specific lesion of the aorta it would have been recognised before now. Syphilis is admitted to be a cause of degeneration of all parts of the body, and the more it affects the constitution the deeper are the tissues attacked by it. How is it that the aorta, on Mr. Welch's showing, is alone affected of all the deeper tissues? Mr. Myers further pointed out that at Netley men were received chiefly from foreign parts, who were the subjects frequently of a complication of diseases, of which syphilis might be one; but how could it be said in such cases to be the origin of arterial lesions? He believed rather that aortic aneurism was due to the strain put upon the vessel chiefly by constriction from the outside. The parts at which aneurism occurs are parts which are most subjected to the blood-pressure when the circulation is impeded. He admitted the existence of syphilitic degeneration of the arteries as distinct from atheromatous degeneration, but thought it did not bear any specific characters.—Dr. Drysdale would have liked further details on the cases alleged to be syphilitic. In reply to Mr. Carter's query, he would say that it was not of the least importance whether the subject of an aneurism had suffered from a slight or an aggravated attack of syphilis. He had seen cases of aneurism undoubtedly attributable to syphilis. Syphilis, with slight external manifestations, was no less dangerous than when the disease was more manifest.—Sir William Gull said that he must take great exception to the use of the word "node" as applied to the arterial degeneration referred to, for he doubted much if there was any pathological distinction between this form of arteritis and other forms. Indeed, the author of the paper admitted that the same nodular condition of the aortic lining membrane occurred under other states. Then a syphilitic lesion is something very characteristic—e. g., a syphilitic rash has certain characters stamped on it, by which it is at once recognised as specific. Therefore if these same arterial inflammatory changes can be attributed to rheumatism and to alcoholism, then it would limit the part played by syphilis to a predisposing cause. He was surprised to hear Dr. Drysdale say that he had seen cases of aneurism due to syphilis.—Dr. Drysdale: "I meant cases of aneurism in syphilitic subjects."—Sir Wm. Gull: "There have been many cases of aneurism then due to syphilis." Mr. Welch seemed to regard aneurism of the aorta as a sort of syphilitic tumour. He (Sir William) believed that those cases of reputed aneurism which were said to be cured by iodide of potassium were really not aneurism at all. They were examples of mistaken diagnosis. He had seen one case in which an abdominal aneurism was said to have been so cured. But of what value are such statements unless confirmed by post-mortem observation? Before then admitting the therapeutical efficacy of iodide of potassium in such cases, the diagnosis of aneurism must be undisputed, and that it can only be by subsequent dissection. He believed that syphilis was a cause of aneurism, but probably only indirectly so. What proof had Mr. Welch, besides the disease in the aorta, that his subjects were syphilitic? Were there undoubted syphilitic lesions in the other viscera? The weakened and degenerated state of the heart in aneurism was doubtless due to the kind of life such patients were obliged to lead.—Mr. Welch, in reply, said that he was not surprised at the doubts that had been expressed, for before he took up the subject he himself would have been surprised at the results he obtained. His cases were based upon the life history, taken from registration reports, in which each time the man is ill that fact is recorded, as well as the kind and degree of syphilitic infection, if any; and also upon the post-mortem data, drawn up by men who were not acquainted with the previous history of the case. In nearly all his cases there had been primary syphilis, followed by eruption on the skin, glandular affection, and periosteal nodes. The lesions in other parts found after death embraced indurated glands, nodes on the cranium, and often cirrhosis or gummata in the testicle. The absence of other lesions he had explained in his paper by the fact of the aortic disease leading to early death. Nor were any of these men the subjects of other disease, as Mr. Myers had suggested, nor had they been so in their life history. The fact of the arterial changes being syphilitic was not altered whether the changes were called "nodes" or not; nor was that fact set aside because a small proportion of cases could be referred to other influences, not syphilitic. A periosteal node was not solely produced by syphilis.

The Society then adjourned.

OBSTETRICAL SOCIETY OF LONDON.

At the meeting on November 3rd, 1875, William Overend Priestley, M.D., F.R.C.P., President, in the chair, the following gentlemen were elected Fellows of the Society:—John Ford Anderson, M.D., R. S. Fancourt Barnes, M.B., John Branson, L.S.A. (Rotherham), and William Stewart, L.R.C.P. Ed. (Barnsley). The President announced that Dr. Farre had accepted the Honorary Presidency of the Society.

Dr. Edis exhibited an Infant with Hydrocephalic Head, which impeded delivery. It presented by the breech. Traction upon the trunk failing to accomplish delivery of the head, Dr. Edis was sent for. Examination of the abdomen showed that no second child was present, so that the question of twins with locked heads was negatived. The patient was a pluripara, and vaginal examination failed to detect any deformity of the pelvis. The child being dead, and the head evidently much enlarged, perforation behind the right ear was effected, a gush of clear fluid confirming the supposition that had been made that the case was one of hydrocephalus. Delivery was then readily accomplished. The head, when distended with fluid, measured seventeen inches in circumference. The patient convalesced normally. The placenta had been examined microscopically by Dr. Coupland, who failed to detect any change in its structure throwing light upon the case.

Dr. Protheroe Smith exhibited a Fœtus of six months and a half, the subject of General Dropsy. The mother, aged thirty-five, had previously had three living children born, three miscarriages, and three premature labours at the twenty-sixth week following each other, the last of which was now shown. In the last two pregnancies she had suffered from albuminuria and liver derangement. Before the eighth labour the patient was kept lying up and well fed; before the last she got about and was thin. On both occasions there was incompressibility of the pulse and flushing of the face, and the labour was attended by considerable hæmorrhage both before and after. The body of the fœtus was anasarcous, there was a large quantity of clear brownish-yellow fluid in the peritoneal cavity, and also some fluid in the pericardium and pleural sacs; the kidneys were healthy; the placenta was large, and consisted of only the fœtal portion.—The President inquired whether there was any trace of syphilis in the mother, and whether the œdema existed during the life of the fœtus, or was only a post-mortem appearance, the result of decomposition.—Dr. Smith replied that the fœtal heart had been heard the day before birth.—Dr. Braxton Hicks inquired whether there was any symptom of obstruction to the funis, to which Dr. Smith replied in the negative.—Dr. Snow Beck stated that the fœtus when born was in such a fresh condition as to preclude all idea of decomposition.

Mr. Lawson Tait related the particulars of a case of General Dropsy in a Fœtus, where the skin was so tense that it was not possible to bend the limbs without risk of bursting the skin. The scalp was so distended that the bones could nowhere be felt, and, in fact, the head had been mistaken for the breech during labour. The abdomen was enormously distended by highly albuminous fluid, as also the pleuræ and pericardium. The placenta was large and very œdematous. The cause of the general dropsy seemed to be the premature closure of the channel between the auricles, there being no direct opening between the auricles through the foramen ovale.—Dr. Protheroe Smith considered this to be evidently a disease primarily and altogether of the ovum, whereas in his own case the disease had originated from the disordered health of the mother. He would like to know whether any of the fellows had met with similar instances—hyperæmia with liver derangement. There was in his own case great peculiarity of the pulse, which was extremely incompressible. The mother's lips were of a crimson tint, and she had had several abortions. One patient, who had aborted seven times, he had bled once, and she went to full time. In his case he had tried abundance of fruit and wine in one pregnancy, and exactly the reverse in the other, the result being the same in both. He had witnessed in a few cases frequent consecutive abortions, at about the fifth and sixth month, arrested by venesection, and followed in succeeding pregnancies by living children.—Dr. Madge said he could hardly accept Dr. Smith's explanation as to the cause of the death of the fœtus. He had given considerable attention to the subject, but he had never understood that a common disease or derangement of the liver in the mother could affect the child in utero in a somewhat similar way. It was well known that the mother may be morbidly affected in many ways, even with albuminuria resulting in convulsions, and still give birth to a perfectly healthy child. A syphilitic history, if such existed, might afford an explanation. The fœtal liver, receiving the tainted blood direct from the mother, became affected with syphilitic inflammation, and deposits leading to obstruction of the portal system and ascites.—Dr. Routh inquired if there had been any specific examination of the foramen ovale of the first child.—Dr. Heywood Smith replied that the heart, on examination, was found to be perfectly normal. The last three times pregnancy had ceased at the twenty-sixth week, showing that there was some disease of the ovum. The liver was also disordered in former confinements. He would be glad if any Fellow of the Society could throw any light upon the intermittence of the albuminuria during pregnancy.—Dr. Snow Beck remarked that he had the opportunity of examining both Dr. Smith's cases, and had also seen two other very similar specimens. The clinical histories had been very much alike: healthy living children at first, then premature expulsion of dead fœtuses about the sixth month, presenting evident signs of previous and serious disease. Effusion of fluid into the peritoneal cavity existed in all, far too large in quantity to be the result of post-mortem change. The organs, excepting the liver, were healthy; this was paler than normal, soft, readily torn with the finger; the liver-cells being much broken down. The parents were singularly free from even the suspicion of a syphilitic taint. The effused fluid was too large and too generally diffused to be caused by any mechanical disturbance of the circulation. The only probable explanation of this condition of the fœtus appeared to be from some deficient or altered state of the nutrition, whether fœtal or maternal it appeared impossible to determine from the facts at present known.—The President said that in considering the pathology of these cases it was well to bear in mind that the subcutaneous cellular tissue in children after birth was prone to become œdematous from the infiltration of serum in certain depressed conditions of health. It was no uncommon occurrence in hospitals to find children, who had been ill-fed and exposed to adverse influences, the subjects of a general œdema, which might proceed to an extreme degree, without such malformation or disease as to account for it. The villi of the placenta in Dr. P. Smith's case had the appearance of being atrophied, and he might suggest that possibly the œdema in the child was due to its imperfect nutrition in utero, and to the passive congestion this induced.

Dr. J. G. Swayne, of Bristol, brought forward a communication "On a New Form of Blunt Hook and Sling, for assisting Delivery in Cases of Breech Presentation." The instrument consisted of an ordinary blunt hook, with the end curved back upon itself, so that a loop could be hitched upon it. When the hook was withdrawn after being passed over the groin, the sling, consisting of a piece of strong silk cord, with a loop at each end, was left *in situ*. Traction was then made in the usual way, and as the sling was padded there was less risk of injuring the soft parts of the child than when the ordinary blunt hook was employed.—Dr. J. Braxton Hicks thought that in the use of the blunt hook sufficient attention had not been given to the assistance afforded by external pressure, applied to the fundus uteri, in breech cases, and the delivery of the aftercoming head through the brim. He thought half the strain was taken off the thigh, and that without undue crushing of the uterine wall, by the hand pressure. Text-books generally omitted to notice the great help given, and although he had no doubt some practitioners employed extreme pressure, yet very frequently it was never thought of, but all the force was put upon the hook.—Dr. Madge had had reason to be dissatisfied with the blunt hook. He was afraid that in any case when much force was required some injury must be inflicted, whatever the plan adopted. He had suggested covering the hook with india-rubber, compressed sponge, or wash-leather. If this could be properly carried out it would probably be a safer instrument than Dr. Swayne's, and could be much more quickly and easily applied.—Dr. Aveling remarked that the life of india-rubber was only about three years; it then became brittle, and if put aside would be found useless. He feared therefore that the suggestion, though ingenious, was not very practical.—Dr. C. Godson agreed that whenever a foot could be brought down, in impacted breech, it was the best plan to adopt; but where this was impossible the hook must be employed. He had recently tried that known as Lazarewitch's, but found that the bulb at the extremity of the hook was the point which received the force applied, and pressed severely upon the tissues. He regarded it as a dangerous instrument. In one instance the skin had been cut through, and much bruising of the surrounding soft tissues produced by its employment.—Dr. Lawrence had seen a case where the saphena vein had evidently been lacerated from the use of a blunt hook. The sling was far less likely to cause injury.

Dr. George Roper read a paper "On Prolapse of the Funis during Labour," tending to show that this accident was rarely primary, but mostly the result of some other abnormality. After alluding to the various conditions predisposing to this complication of labour, and mentioning the different methods of accomplishing reposition, he stated that the real difficulty consisted in keeping the cord within the uterus after it had been returned. The best means of doing this seemed to be in securing the firm adaptation of the presenting part to the os uteri. The question of turning in place of forceps was then considered, the author preferring the latter method, considering that there was less shock to the mother. Reports of six cases were given, the author concluding by stating that prolapse of the cord is for the most part associated with some other complications of labour, and that it behoved us to make observations as to what that complication might be, as the management of the cord would in a great measure depend upon the nature of the complication; in some cases the funis could be saved from pressure, in others not.—Dr. Braxton Hicks had employed cephalic version in transverse presentations with prolapse of the cord, using one hand externally to press down the presenting part into the os uteri, the funis being pushed up simultaneously by the internal hand.—The President inquired if Dr. Hicks combined the postural method with reposition of the cord.—Dr. Hicks replied that he had not found it necessary. He had experienced no difficulty in pressing up the head and carrying the cord up by the same hand as quickly as possible, and then the outside hand pressed the head into the os. In prolapse with head presentation, pressing the breech to the fundus is not needed as in transverse presentations. —Dr. BRUNTON thought Dr. Roper had not given sufficient prominence to the postural method. He (Dr. Brunton) had found it the most satisfactory of all methods of treatment of prolapse of the cord, and considered it applicable in all cases. He questioned whether Dr. Hicks would be able with his middle finger to reduce a long loop of cord protruding from the vagina; by the postural method this could be done.—Dr. EDIS called attention to the correct postural position being the genu-pectoral or knee-shoulder, not knee-elbow position, as had been spoken of by many.—The PRESIDENT referred to a paper read by Dr. Thomas, of New York, some eighteen years ago.—Dr. ROPER asked what was the *rationale* of the postural position; gravitation would not account for it.

Mr. LAWSON TAIT read a note on a "Diseased Placenta." The author narrated briefly the outlines of a case. The patient, aged twenty-nine, miscarried three months after marriage. She next bore a child at full term, which died of convulsions three days after. She next miscarried between the sixth and seventh month, and again between the seventh and eighth month, the child being alive. When one month advanced with the next, Mr. Tait put her upon chlorate of potass and perchloride of mercury, and she went her full time and was delivered of a healthy living child. The chief point of interest was in the appearance of the placenta. It was disproportionately small to the size of the child, and fully two-thirds of its surface had undergone a peculiar change. This the author had examined most minutely, and described most thoroughly, the communication being one of much scientific interest.

Reviews and Notices of Books.

Nouveau Dictionnaire de Médecine et de Chirurgie Pratiques. Tome XX.: LACRYMALE GLANDE—LUXATION. Paris: Baillière and Son. London: Tindall and Cox.

THIS volume contains, amongst others, the following important articles:—"Langue," by MM. Demarquay and Rigal; "Lait," by M. Straus; "Larynx," by Bœckel; "Lépre" and "Lichen," by M. Hardy; "Leucocythæmie," by MM. Jaccoud and Labadie-Lagrave; "Leucorrhœa," by M. Stoltz; "Lèvres," by M. Laugier; "Lit," by M. Poncet; "Lithotritie," by M. Demarquay; "Luxations," by M. Valette; "Ligatures," by M. Sarazin.

The volume opens with an exceedingly good article by M. Od. Lannelongue on the Anatomy, Physiology, and Surgery of the Lachrymal Gland and Apparatus. The difficult point of the cause of the entrance and descent of the tears through the small canaliculi is, according to the author, satisfactorily explained on the theory of Ross, which is that the orbicularis in closing the eye contracts from without inwards, and thus drives the tears into the lachrymal sac. The symptoms of true fistula lachrymalis are given, and the several methods of treating it, including that of von Graefe, which consisted in removing the lachrymal gland (rather a heroic measure for so small a disease) are described. The author, however, has not noticed the very ingenious method suggested by Mr. Hulke some years ago in a case that came under his care, in which he re-established the normal opening, whilst he closed the cutaneous one. The subject of inflammation of the lachrymal sac is described in accordance with Mackenzie's division, and the author very honestly confesses that neither internal nor topical applications are of much service when the inflammation has fairly set in. In performing the little operation of slitting up the canaliculus, M. Lannelongue recommends that the *upper* duct should be divided. Speaking of the origin of obstructions leading to abscess, accompanied by disease of the bone, M. Lannelongue is in accordance with Wecker and with our own experience, that the disease of the bone in many instances is not the result of the violence of the inflammation, but that the bone or periosteum is the part primarily affected either from scrofula or syphilis. He approves strongly of the injection of medicated fluids through the canaliculi in the early stages of the affection, practised with a view of modifying the mucous membrane. We fancy it is but rarely practised in this country. He recommends strongly Stilling's proceeding for obstruction in the lachrymal sac, which consists in slitting up the canaliculus, and pushing down the duct a knife with a peculiarly-formed narrow triangular blade, turning the instrument once or twice, so as to divide new portions. It is founded on the supposed presence of muscular fibres in the walls of the canal, the incisions allowing them to retract. The success is stated to have been very great in the hands of more than one distinguished operator.

The articles "Langue" and "Larynx" exemplify well the progress that has been made during the last thirty or forty years in special departments of surgery. On referring to "Cooper's Dictionary of Surgery," published in 1838, we find only four pages devoted to the consideration of the affections of the tongue, whilst in regard to the diseases of the larynx the only reference made to them is included in the article on "Laryngotomy." In the volume before us these two subjects occupy just one hundred pages each, and contain a large amount of information in regard to the varieties, causes, symptoms, and treatment of numerous affections that, if not always capable of being successfully dealt with, are now diagnosed without difficulty.

The article on the "Tongue," by MM. Demarquay and Rigal, commences as usual with an anatomical description, which is sufficiently accurate, though some objection might be raised on embryological grounds to the propriety of calling the hyoid bone the skeleton of the tongue. An interesting section is devoted to the function of the organ and of the nerves supplying it. M. Demarquay states that he has been able to trace the chorda tympani beyond the submaxillary ganglion, beneath the mucous membrane of the dorsal surface. There seems to be reason for believing that it is distributed to the vessels with branches of the sympathetic, and this may account for some of the peculiarities in the sense of taste observed in cases of paralysis of the seventh. The pathology of the tongue is considered under the following heads:—(1) Vices of conformation, (2) inflammation, (3) abscess, (4) gangrene, (5) wounds, (6) burns, (7) the pustule maligne, (8) ulcers, (9) foreign bodies, (10) tumours, (11) constitutional affections; and several of these are subdivided.

Under the head of "Larynx," an account of the anatomy and physiology of this organ is given by Eugene and Jules Bœckel, with a woodcut showing the appearances presented by a vertical transverse section of the vocal cords. The varieties of the laryngoscope are fully detailed, with the difficulties that attend its use and the mode of overcoming them, which are illustrated with appropriate diagrams. The writers enter into the consideration of inflammations of the larynx. They describe the symptoms and pathology of laryngitis, but, curiously enough, dismiss the subject of its treatment half contemptuously with the observation that it is "*connu de tout le monde.*" This omission is, however, supplied in the remarks that are subsequently made in regard to œdematous laryngitis, &c. We do not find the value of emetics dwelt upon, though an emetic and a full dose of quinine will sometimes cure a severe case of laryngitis. The bibliography of this article is extremely well given.

The article on Leucocythæmia is very instructive. The term, as the authors, MM. Jaccoud and Labadie-Lagrave, remark, invented by Bennett, really indicates only a symptom of a much larger and wider disease, and, by directing attention to the symptom and not to the primary dyscrasia which produces it, long retarded the advance of knowledge. They prefer the terms "generalised hypertrophy of the lymphatic ganglia," suggested by Cossy, and "lymph adenoma," proposed by Wunderlich. The proportion of 1 white to 335 red corpuscles, which is regarded as the norm by Moleschott, has been in exceptional instances raised to 1:2, and in one case to 1:1 (Isambert). In one extraordinary case Welcker estimated that there were only 2,000,000 red corpuscles in the whole body. It would appear that the microscopic examination of the blood will alone suffice to diagnose paludal cachexia from that of lymphogenic origin. In the former the blood almost invariably contains black pigment, but additional signs may be found in the absence of enlargement of the glands, and in the history of exposure to marsh miasm. The peculiar characters of the urine are dwelt upon, especially the deficiency of urea and the excess of uric acid, and M. Jaccoud asks whether this is not referable to the oxidation of the hypoxanthine which the blood of leucæmic patients almost invariably contains.

Fifty pages and a dozen woodcuts are devoted to the subject of "Ligatures," which are considered first generally, and then specifically by M. Sarazin. The difficulties experienced in tying a wounded artery when the tissues, in consequence of being swollen and infiltrated with blood, are almost unrecognisable, are forcibly depicted, and he gives an instance where he tied the subclavian for a wound of the axillary artery, and, after a few days, the bleeding recurring, he was obliged, under much more unfavourable circumstances, to cut down and tie the artery above and below the seat of injury. No allusion is made to Lister's carbolic acid atmosphere, which is so important an adjunct in dealing with such cases as these.

The important article "Lithotritie" is the joint production of Demarquay and Cousin. Like all the other longer essays in this work, it is preceded by a short historical *résumé* in which the salient points are given. The first notice of lithotrity seems to go back to the beginning of the ninth century, when a monk, being tormented with a renal and vesical disease, introduced instruments *per vias naturales* into the bladder, and, having broken down the stones he found there, extracted the fragments. It was not, however, till 1823 that lithotrity became a practicable operation, owing to the ingenuity and perseverance of Leroy d'Etiolles and, after him, of Civiale and Heurteloup. Illustrations are given of the various forms through which the instrument has passed, from the days of its infancy to the present time, both in France and England.

A Guide to the Microscopical Examination of Drinking Water. By J. D. Macdonald, M.D., R.N., F.R.S., Deputy Inspector-General of Hospitals and Fleets; Assistant-Professor of Naval Hygiene, Army Medical School. With 24 Lithographic Plates. London: J. and A. Churchill.

Dr. Macdonald has given us a work which will prove of great use to medical officers of health. He has drawn with pen and ink on lithographic paper, and has then transferred to stone, the chief objects seen in the sediments of drinking water. By adopting this plan of drawing he has been able to give no less than twenty-four plates at a very small cost. He has first drawn the mineral substances, then the dead vegetable or animal structures which commonly pass into water, and then the living plants and animals which are more or less found in all waters. His object is, he tells us, to enable these various bodies to be easily identified by the observer. He has not attempted to decide whether any of them are hurtful or otherwise; he considers this to be a point for future inquiry, and at present he has merely attempted to give medical officers of health a means of making out the nature of what they see on microscopic examination of sediments in water. With the exception of the plate of Bacteria (Plate 6), which is copied from Cohn, and a few others where specimens could not be procured, all the drawings are original, and from waters examined by the author. Considering especially how they have been drawn, they are marvels of artistic skill, and some of the plates are quite beautiful. They are not, of course, coloured, as this would have made a costly instead of a cheap book, and the object has been to provide a work which all can purchase. The letterpress is placed at the end, and is so arranged as to render the identification of the objects easy even to those who are not familiar with the microscopic world in water. For example, in Plate 15 (not Plate 14, as stated by a press error at page 42), the monads are drawn; at page 42 will be found the means of identification, given in a tabular form, and so arranged as to present no difficulty even to a beginner, as the numbers in the tabular statement are identical with those on the plate. Henceforward no medical officer of health need close a report on water by observing that it contains "floating organisms"; he may, if he pleases, identify almost every form, except possibly the immature or transitional states.

It is clear that this identification is a necessary preliminary to the inquiry as to whether particular classes of plants or animals in water indicate particular impurities, or whether they are connected with special diseases. These are inquiries of singular importance, and have all to be still worked out. By this publication Dr. Macdonald has greatly advanced our means of attacking these difficult problems, and we do not doubt that medical officers of health will feel grateful to him for his timely and useful little work. We hope, indeed, that this book may lead young microscopists generally to study the world of waters; they will find it a very good introduction to this part of zoology.

Chemistry: General, Medical, and Pharmaceutical; including the Chemistry of the British Pharmacopœia. By John Attfield, Ph.D., F.C.S., Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain. Sixth Edition. London: Van Voorst.

Professor Attfield's manual is so well known and so universally admired and used that it is hardly necessary to do more than notice the appearance of another edition, carefully revised and illustrated, for the first time, by woodcuts. The book is a storehouse of well-arranged and accurately-stated facts. The methods are judiciously chosen and clearly described, and altogether students of pharmacy and of materia medica may well be congratulated on having for their guidance so excellent a text-book.

MORTUARIES IN THE METROPOLIS.

To the Editor of The Lancet.

Sir,—As I am desirous of making out a complete case for legislative action on the question of the establishment of mortuaries in the metropolis at the forthcoming deputation of the Strand Board of Works to the President of the Local Government Board, will you permit me to request the medical officers of health, Poor-law medical officers, and others, to forward me any information they possess as to the evils that arise from the want of such accommodation.

I am, Sir, your obedient servant,
33, Dean-street, Soho, Nov. 22nd, 1875. Joseph Rogers.

We are asked to state that the Provisional Committee of the British Medical Defence Association invite the attendance of medical practitioners at a meeting to be held at the Medical Society's rooms, Chandos-street, Cavendish-square, on Tuesday afternoon next.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 27, 1875.

DURING the past few years a custom has grown up at some of our leading Medical Societies which, if it were only carried out on certain definite and fixed principles, might aid greatly in the advancement of knowledge on many vexed questions in Medicine. We allude to the institution of discussions on subjects of stirring interest, where much difference of opinion prevails. Such debates have an intrinsic value in themselves, as they give opportunities for the expression of their views by individual workers on the subject; and it might have been thought that the result would have been something tangible and satisfactory. But it is much to be questioned whether they have hitherto really produced so much benefit or added to our resources in the treatment of disease as much as they might reasonably have been expected to do. In reviewing the subjects that have been so treated we find, in the first place, that we have learnt many different views on the subject of tubercle in its anatomical relations to phthisis—views expounded by men who had devoted much time and study to the question, and whose opinions on such a subject carried much weight with them. We have had an equally luminous exposition of the views held upon the kindred subject of cancer in a debate which only served to show how wide was the gulf between those who adopt the theory of its local origin and those who deem it to be the expression of a constitutional disease. We have had similar divergence of opinion on the subjects of pyæmia and puerperal fever in debates the result of which was, we venture to state, no more satisfactory than in those which preceded them. Then we have had the germ theory of disease discussed in a manner which left the one side victorious, less, perhaps, by reason of the preponderance of facts than because the opposite views were so little and so feebly advanced; and, finally, within the last few weeks we have witnessed an attempt—abortive it is true, and stifled in the birth—to elicit the opinions of metropolitan surgeons as to the value of the plan of treatment known as antiseptic. We have had all these subjects fully expounded in a series of speeches, many delivered after careful preparation, and some even clothed in an eloquence which it would have been thought could scarcely have been made to cover the bare details of science. We may well ask ourselves, now that we are on the eve of another debate dealing with a most important subject,—How much have we gained by them? Is the subject of puerperal fever, for example, settled now once and for all?—and are all men of one mind as to the nature and origin of that disease since the long debate at the Obstetrical Society last summer? Is there but one opinion now prevailing as to the origin of cancer?—or, at least, have we gained a clearer insight into the nature of this disorder? Surely not; for, even putting out of question the one-sided character of some of these debates, the result has been in most cases to leave individual opinion much in the same position as before they were started. How many, for example, did Mr. DE MORGAN convince by his logical and closely-reasoned argument in favour of the local origin of cancer?—for on this question opinion was so equally divided that anyone who had before framed his views on the subject can have seen no reason to change them. Thus unsatisfactory as the issue has been in the past, bewildering as has been the conflict of opinion to him who has sought for light where he has had most reason to expect to find it, we must confess to view with some misgiving the prospect of another debate on a subject which it is notorious is one on which much diversity of opinion exists. We can safely predict that, if the forthcoming debate on syphilis be pursued on the same principles as those discussions we have already experienced, the profession will have gained but little from its having taken place.

It is certainly, then, time to see if there cannot be devised some means by which such debates might be rendered more profitable. We have before now indicated some of the paths which it is desirable that these discussions should take, so that on their termination we may be left with some fixed opinions, some definite and precise conclusions.

In the first place, it is incumbent upon the Society in which the debate takes place that the subject matter of the debate should be strictly confined to the objects for which the Society was founded. If it be desirable to treat the subject from a clinical point of view, the facts adduced should be strictly the result of bedside observation. If the pathology of the subject discussed be in question, to the consideration of its pathology, and of that alone, should the debate be limited. Hence the obvious necessity of fixing clearly beforehand the limits of the debate and the branches of the subject to be discussed. Without some such guidance, the speakers will, like ARTHUR's knights, pursue "wandering fires" and lose themselves in the quagmires of vague hypothesis.

In the next place, the debate should be wound up by an authoritative statement, embracing the views of the various speakers, and enabling the hearer to judge of their relative value and importance. At present, a host of heterogeneous opinions, emanating from men whose opinions are indeed of great individual weight, are flung down before the profession *en masse*, and perhaps even the very authority they bear renders the task of elucidating the truth of greater difficulty. We by no means advocate such a conclusion as might be obtained by a division being taken at the close of a debate; for, even if such a solution to the difficulty were desirable, it would often be impossible, so varied and numerous are the "amendments" that crop up one after another on the propositions laid down by the opener of the discussion. But a definite conclusion might fairly be arrived at, if it be made incumbent on the president to close the discussion by gathering up the chain of evidence and laying before the Society the points of agreement and difference in such a manner as would enable the profession to arrive at a reasonable and just verdict, and to feel satisfied that their conclusions were right. One manifest objection to such a course might be found in the disinclination of the president to adopt it. He may feel, and rightly too, that he was himself more or less of a partisan, and would thus be unable to present the facts in as impartial a manner as if he were on the judicial bench; and it would perhaps be too much to expect this of him. But, failing this, we do not see why, in questions of such great import as those that have already been discussed and as that which is shortly to be reviewed, a committee of the Society should not be appointed to report on the whole debate, and draw certain broad and specific conclusions from the facts adduced on all sides. It is premature yet to point out the example of the Medical and Chirurgical Society in this respect, although we have no doubt the Council will accept the recommendation of Dr. WEST to refer the subject of Croup and Diphtheria to a committee. It can only be in this or some other similar manner that we can hope to arrive at unanimity, or rather stability, of opinion, sufficient to guide the feet of those who now lose themselves in the maze of individual views.

That some such scheme is desirable there can be little doubt; and that it is practicable there is ample evidence in the proceedings of other scientific bodies both in this country and abroad. Certainly of the value of these debates there can be or ought to be no two opinions. The time has arrived when from the stores of accumulated material we may fairly hope to gain some important general facts and principles to guide our daily practice. But if such debates are to have any real and permanent value—if they are to mark an epoch in the history of medicine, and are not doomed to be recorded as a congeries of individual views tending no whither,—then some such reform in the conduct of them should be at once initiated. In one Society, at least, the debate has become an annual institution; and here, if anywhere, it is desirable that its results should be settled and enduring (so far as the shifting basis of the science will allow). If, on the other hand, this annual debate be conducted in the future as it has been in the past, it will not ensure the objects for which it was started, and will leave but little lasting impression on, and produce but little advantage to, the profession at large.

◆

THE intention and ingenuousness of Mr. MARSHALL'S proposal to institute a compulsory examination in Anatomy at the Royal College of Surgeons of England at the end of the first winter session, are so laudable that it is a duty far from pleasant to be compelled to say anything unfavourable of the scheme. But in the interests of medical education we feel bound to point out the fallacy of its guiding principle. In estimating the merits of the project we must, however, be careful not to mistake the will for the deed. Mr. MARSHALL'S prime object is to make sure that the knowledge, and especially the knowledge of anatomy, acquired by candidates for the diploma of the College of Surgeons shall be not only more extensive, but sounder than it has hitherto been. This desire is in itself highly commendable, but not original or peculiar, and is probably participated in by every member of the profession. It is as to the mode in which it is proposed to secure these objects that any serious difference of opinion exists.

Many of the evils to which Mr. MARSHALL has drawn attention in his memorandum are, alas! too rife. Everyone engaged in the tutorial departments of the medical schools knows well that much valuable time is wasted by many first-year's students; and that the knowledge acquired by the candidates for the College examinations is not only deficient, but unsound and evanescent. The question is whether matters would be improved by compelling students to prepare for an elementary examination at the end of the first session in one and only one of the subjects in the prescribed course of study for that term. Experience says no! The experience of most competent authorities in educational affairs, and the experience of the College of Surgeons itself, have shown that such a course would be the surest means of defeating the real objects of education. It is no exaggeration to state that the certificate and examinational systems of the College have done more to damage the cause of medical education in this country than anything else. Professional grinding and its attendant evils have been the direct outgrowths of the hampering regulations that have been imposed upon students by the Council of the College, and of the unsound method of testing the students' knowledge. While the Council has always vainly flattered itself that if its curriculum has been carried out the efficient training of the student has been secured, the cause of true education has suffered. Not only have regulations in many instances been systematically evaded by teachers and pupils, but, even where they have been complied with, evil rather than good has resulted. Students have worked for examinations, and the knowledge thus acquired has been unsound and of little permanent value. A certain number of facts have been "crammed" within a limited space of time; but there has been no mental assimilation, no organic registration of ideas,—and what had been learnt has been speedily forgotten. The College examinations have proved quite worthless as tests of the candidate's reason and judgment, and even of his training, and serve only as exercises of memory and of coolness and self-possession. It is as Dr. WHEWELL has affirmed: that when the student works for examinations only, "he does not wish to understand, but to appear to understand"; and any teacher of anatomy can testify that those who can put on the best appearance at the College are the most likely to succeed. When we consider the nature of the examinations and the constitution of the Board of Examiners at the College of Surgeons, it is not difficult to account for these things. Not only is the time allotted to each candidate quite inadequate, but the tests themselves are wanting in uniformity and appropriateness. A spirit of indifference and recklessness has been engendered in students; and professional grinding, which has made now its way in its most objectionable forms into the medical schools, has been encouraged. The quality of the instruction has also, with a few honourable exceptions, gradually deteriorated and sunk to the level of the knowledge of the examiners, most of whom have taken no part in the practical teaching of anatomy or physiology for many years, if at all, and retain only the crude notions of their early years, uninformed, or, what is worse, misinformed concerning later acquisitions and recent advancements. The examinations at the College of Surgeons are acknowledged on all hands to be, as far as the educational purposes and tests of knowledge are concerned, monstrous failures, if not actual impositions. We could at the present moment state at least a dozen instances in which within the last two years students thoroughly trained and well educated, of high culture, and great distinction as prizemen and honoursmen at the various schools and colleges in the United Kingdom, have been rejected at the College of Surgeons, while the veriest pretenders have passed creditably. Yet it is this system, from which such results may arise, that Mr. Marshall would use for the improvement of medical education. It is greatly to be regretted that a teacher and examiner of Mr. Marshall's position and influence should not have attempted some radical reform, instead of endeavouring to patch up a system that is old and rotten, and must sooner or later inevitably succumb to the force of enlightenment and progress. Mr. Marshall proposes to remedy the evils that have been produced as a direct result of the pernicious regulations of the College and of the faulty system of examinations by extending the operation of the morbific influences. He would hold what he terms short elementary examinations in anatomy, the examination consisting of two parts, a written and a *vivâ voce*. In the written examination two hours or less would be allotted to the answering of four questions, while the *vivâ voce* would not extend at most over more than fifteen minutes, and it might be considerably less. This would surely be playing at examination. No good could possibly come of such an imperfect test, even if it were not destructive of all previous study. If an elementary examination were instituted, its standard could not be made higher than that attainable by dull students, for, if it were, it would be unjust, and if it were not, it would only thwart the efforts of the quicker and more intelligent students. The evils of the levelling-down system would therefore be greatly multiplied. But there is another fallacy by which Mr. Marshall's scheme is marred. It assumes that the knowledge of the first-year's students is complete. The fact is that the first year's instruction at the best schools is preliminary to that of the second year, and the knowledge of the student is, as it were, embryonal, and should be regarded as merely an early developmental stage of a subsequent complete knowledge. But even if the knowledge be complete as far as it goes, it is, in the vast majority of cases, confined to so small an area that it would be impossible for the student to present himself even at an elementary examination on the anatomy of more than a very small portion of the human body. If the average student were to present himself for such an examination as Mr. Marshall suggests, it is certain that he must have hurried over his work in a manner altogether inconsistent with any accurate and sound knowledge. For the first two months of his career the student flounders in the elements of the subjects of study, and has to acquire a vocabulary of technical and scientific terms. At least one clear month must be given to the study of osteology and histology, without a knowledge of which no progress can be made in either anatomy or physiology. But even when these difficulties are overcome, others present themselves. The supply of bodies is so scanty and irregular that in large schools two or three months elapse before each student can be supplied with even one part for dissection. Let us take an example by no means unique. To a large anatomical class numbering nearly two hundred students, twelve bodies have been supplied by the Inspector of Anatomy since the commencement of October. Now, as twelve bodies will furnish parts to only about one hundred men, it follows that long before the second hundred can be supplied with parts, the first hundred have finished their work, and are compelled to remain idle, as far as dissection is concerned. It is, therefore, impossible for the majority of first-year's students to get through the dissection of the limbs before the termination of the first winter session, unless means are adopted for securing a large and regular supply of subjects to the large schools. Where there are about one hundred new students, twenty-five bodies will be required to commence with—that is, four students to each body; and as each student will be required to dissect an upper and a lower limb, it follows that in the course of the winter session at least fifty subjects will be required for the first-year's students alone, over and above the bodies required for the purposes of instruction and demonstration and for the second and third year's students preparing for the first professional examinations at the College of Surgeons and elsewhere. Unless the Inspector of Anatomy can undertake to supply at least five or six hundred subjects to the medical schools in one session, it is manifest that Mr. Marshall's proposal is quite impracticable, and if insisted on will lead to a cramming of anatomy from books instead of patient working at dissection.

◆

A few weeks only have elapsed since we called attention to some very interesting and important researches by Dr. Klein on the Lymphatics of the Lungs having a direct bearing on the process of acute miliary tuberculosis; and we have now to place before our readers the results of an equally elaborate investigation by the same indefatigable observer on the Small-pox of Sheep, a disease that very closely resembles variola in man, and a knowledge of which will undoubtedly materially elucidate our conceptions of the exanthemata generally, showing, as these observations appear to do, that variola, at least, is due to the development of a special form of fungus. The lymph was obtained from Professor Chauveau, and inoculation was practised in the skin of the groin on the 8th of December, 1873. On the 13th most of the punctures were surrounded by a raised red areola; these gradually increased in size till the 15th, when they became depressed and pale in the centre. The temperature of the animals rose at first slowly, then rapidly, but fell when the pocks ceased to increase in size. The pocks were excised at various stages, and immersed for a few days in very weak ($\frac{1}{5}$ per cent.) solution of chromic acid.

Careful examination of the lymph showed the presence of — 1. Minute highly refractive spheres, isolated, or in couples, or in small groups; they correspond to the micrococci of Cohn, and exhibit Brownian movements. 2. Decolourised blood-corpuscles. 3. A few rod-like bacteria, of the types termed by Cohn "termo" and "subtilis." 4. Lumps of a pale transparent substance, with irregularly distributed larger and smaller granules. 5. Several forms of spheres, some larger than the decolourised blood-corpuscles, some smaller. If the lymph be placed in an incubator for twenty-four hours, the pale transparent masses above alluded to become more or less distinctly fibrillar, and appear to consist of a feltwork of very delicate branched filaments, in or on which the highly refractive granules are found, and these in the course of another twenty-four hours become enlarged into the spheres of various size. It is worthy of notice that the few rod-like bacteria disappeared completely after the preparation had been kept in the incubator for twenty-four hours or more. The refractive granules, when small, are of a slightly greenish colour, and proliferate with extraordinary rapidity by transverse fission, forming necklaces, of which the micrococci constitute the beads and a transparent connecting substance the thread. When these necklaces become closely packed, they constitute a *colony* or *zooglœa* of COHN.

On making sections of primary pocks which had only appeared for from six to twelve hours, the characteristic points observed were that the epidermis had undergone considerable increase in thickness, owing chiefly to the swelling of the cells of the rete mucosum. The papillæ of the corium had also become broader and longer. The blood-vessels were distended, the endothelial cells being swollen, distinctly granular, and containing enlarged nuclei. The tissue of the corium, in general, was slightly œdematous, and the lymph-canalicular system larger and more clearly visible; colourless blood-corpuscles had made their way out of the vessels. The general appearances were therefore those of slight inflammation.

Pocks that had existed for twenty-four hours presented all these characters in a more marked condition. The cells of the rete Malpighii had undergone division, and the infiltration of the corium with lymph-corpuscles had greatly increased. In addition, the interfascicular or lymph-canalicular spaces contained a firmly granular material, in which were embedded peculiar ovoid or spherical sharply-outlined structures, containing in a clear substance one large, or two, three, or four small highly refractive bodies. Dr. KLEIN proceeds to contrast these with connective-tissue corpuscles and their nuclei, with pus- and lymph-cells; and shows that by the difference of their microscopical characters and reactions they must be regarded as bodies foreign to the structure of the skin, and, in fact, that they may be regarded as a *fungus*. Many of the lymphatics contained a material composed of a transparent matrix, in which were embedded highly refractive granules; and a few hours later the granules were seen to be arranged in shorter or longer, branched or unbranched filaments. When forty-eight hours had elapsed the granules were found not only to have arranged themselves into filaments, but the filaments had more or less lost their granular aspect, and had become smooth, longer, more branched, highly refractive, and slightly greenish. The mycelium thus formed then fructifies, forming conidia, like an *oidium*. In the earlier stages of the disease it is most abundant in the deeper stratum of the corium; but subsequently it appears in the superficial stratum and in the superficial stratum of the subcutaneous tissue, from which it may be traced for long distances through the lymphatics.

Further observations showed how it comes to pass that the central part of the pock is depressed and pale as regards the peripheral portion. It becomes depressed because a great number of layers of the original rete Malpighii undergo conversion into layers of horny scales, while the deep stratum of the rete grows very actively into the corium; and it becomes pale because the central portion is covered with a thick, horny, dry membrane, formed by the condensed layers of the rete.

Lastly, Dr. KLEIN gives the results of his examination of the pustular stage of the development of the primary pustules; and states that pustulation commences by the formation of isolated vesicles in the rete Malpighii, which, as they gradually increase in number and size, become eventually fused together to form larger cavities and canals. The formation of the vesicular cavities invariably depends on the transformation of individual epithelium cells of the middle layer of the rete Malpighii into spherical or elliptical vesicular structures, possessing a thick membrane and clear contents. As they increase in size the contents come to consist partly of lymph-corpuscles, but principally of mycelium, which may or may not be in fructification. Many of the lymph-corpuscles themselves contain a number of spherical bodies of greenish colour, which appear to be spores.

It would seem from all this that we are now in possession of substantial evidence that variola, if not caused, is at least accompanied, in the sheep, by the growth and development of a peculiar fungus which makes its appearance in the tissue of the corium and its lymphatics, and is gradually carried or penetrates into the vesicles formed in the rete Malpighii. This fungus, Dr. KLEIN proposes, since he has been unable to identify it with any described species, to call the "oidium variolæ"; and adds that it is a very important question, and one deserving alike the attention of physicians and anatomists, whether any form of vegetation corresponding to it is to be met with in the cow-pox or in human small-pox.

Dr. KLEIN'S researches appear in the just issued part of the Philosophical Transactions, and have been communicated by Mr. SIMON, at whose instigation they were made. They are illustrated by most beautifully executed plates.

◆

A VERY proper attempt has been made to pass a Medical Bill through the Parliament of New South Wales. The Bill was a very reasonable one, erring, if anything—especially in the amendments agreed to by its able promoter, Sir ALFRED STEPHEN,—in too liberal concessions made to those weaker brethren, always forthcoming in legislative assemblies, who think it their duty, in the interest of truth and liberty and other exalted principles, to legislate with a special favour to every conceivable crotchet and quack in medicine. Sir ALFRED'S Bill was conceived in the spirit of a professional man and based on the English Medical Bill. That is to say, it forbad the false use of titles, and gave power of recovering in Courts only to such persons as held diplomas or degrees approved by a Medical Council which it provided. It enacted also that no one should be disqualified or refused qualification merely on the ground of peculiarity of medical opinion or theory, so long as his knowledge of medical facts and the sciences fundamental to medicine was ascertained to be satisfactory. Unlicensed practitioners were by one of the amendments specifically exempted from punishment, provided that they put "unlicensed" at the end of any title they used—not definitely forbidden—to indicate that they professed to cure disease.

Such was the moderate Bill by which enlightened men in New South Wales, in the interest of the public, tried to encourage medical education, and give a certain legal recognition to those who had given evidence of possessing it. We are sorry to say that the promoters of the Bill have been defeated, and still more sorry to add that their principal opponent was Dr. SMITH, the Dean of the Medical Faculty of the University of Sydney. It is no part of our wish to intensify the acrimony which Dr. SMITH's conduct in this matter has occasioned. We readily give him credit for not intending to speak disparagingly of the profession or of medical education. Much that he said about the existence of incompetent medical men who had gone through a curriculum and passed the examining boards was of course true. Everybody admits it. But for him to extract an argument out of such a fact against a Medical Bill favouring medical education, and examinations to test it, was an inconsistency which we deeply lament. There are plenty of ignorant people to point out the imperfections of our system of medical education, and to misconstrue the lessons of it, without a Dean of the Medical Faculty coming to help them. Dr. SMITH must know that the only remedy to be relied on for incompetence in the profession is a better education of medical men and a more stringent examination. And these ends can only be secured by some such Bill as that of which he has been the main and too successful opponent. At the time such a Bill as that in question was being discussed he that was not for it heartily was practically against the whole cause of medical science and education.

We can only hope that ere long Sir ALFRED STEPHEN will reintroduce his Bill, and will have Dr. SMITH among his supporters. It is appalling to think what may be the consequences in a colony like New South Wales of leaving everybody that likes to call himself doctor, surgeon, physician, or any other title by which simple people can be misled. If the ignorance of men who have gone through some sort of a medical education is so mischievous, how much more injurious must be the ignorance of those who have had no such chance of being informed. It is really the public that will suffer. Educated medical men may well feel chagrined when a civilised community, led by a Dean of the Medical Faculty, refuses them any special advantage or recognition. But they can provide for themselves. It is the public that will pay the penalty.

MAJOR BOLTON, water examiner, reports that in many of the complaints received by the Local Government Board as to the quality of the water delivered by the metropolitan water companies for domestic purposes, examination has revealed the cause of the alleged contamination to be a dirty state of the cisterns on the premises of the complainants. Major Bolton urges the importance of the frequent and thorough cleansing of all cisterns, and he again points out the danger of gases flowing back into the cisterns, and becoming absorbed by the water, unless the overflow-pipe is brought outside the house, and the end left exposed to the air. We trust that householders generally will practise the excellent instructions given them by the water examiner.

Annotations.

"Ne quid nimis."

THE MEDICAL OFFICERS OF HEALTH OF COMBINED SANITARY DISTRICTS.

THE medical officers of health of combined sanitary districts are beginning to understand more clearly the very anomalous position in which they have been placed by the Local Government Board's administration of the Sanitary Acts upon Poor-law traditions and principles. They find themselves suspended, like a Mahomet's coffin, between a presumed central departmental heaven and an assumed local authority hades, repelled by both alike. It must be confessed that they, in their blind advocacy of the earlier administrative measures of the Local Government Board, and their voluntary and willing acceptance of a position wanting in professional respect, whether as related to the central or to the local authority, have contributed much to the present state of things. But it is astonishing how imperfectly they even now apprehend their true position. They are indignant at having been told in effect by the Local Government Board, in their recent interview with the President, that "as they had made their bed so they must lie upon it," such answer only being possible so long as the present administrative policy of the Board is pursued. They have been made the "cat's-paw" of the Board in its policy of aggrandising the power of its Poor-law elements of administration, and have been thrust to the wall precisely as the Board's own Medical Department has been. Indeed, they have been astutely used in helping to bring about the depreciation of medicine at head-quarters, not seeing that the attitude of the Board in this respect must govern its attitude in a like respect with local authorities. They have been encouraged not to content themselves with administering existing law to the best of their power, but freely to criticise this irrespective of their immature experience, thus exposing themselves alike to discredit from the central and local authorities, and justifying in a fashion most detrimental to themselves the cry against being doctor-ridden. Until medical officers of health take a professional as well as an individual view of their position, they must remain, as they are now, isolated and helpless each in his own district. When they have come to understand that there is a professional as well as an individual aspect of the question, they may carry the whole profession and the public with them, and it will go hard if the present derogatory position which they hold, both with reference to the Local Government Board and the local authorities, is not amended.

METROPOLITAN WEEKLY RETURNS OF MORTALITY.

IT is now rather more than twelve months since the Registrar-General ceased to furnish gratuitous weekly returns of mortality to the metropolitan officers of health after repeated futile efforts to obtain from the sanitary authorities some remuneration for the registrars for copying these returns. This step was the result of representations from the London registrars, that by allowing a gratuitous secondary use to be made of returns furnished for official purposes, they were deprived of fees, for making such returns, enjoyed by registrars in all other parts of England and Wales, and which had been sanctioned by Act of Parliament. Attention has recently been again drawn to this subject by Dr. Gibbon, the medical officer of health for Holborn, in some remarks at the opening of his report upon the sanitary condition of Holborn for the year ending Lady-day, 1875. These remarks appear to us, at the present time, most ill-judged, both because, the matter being now settled, no good can result from further attempts to make justice to the registrars appear, like a grievance to sanitary authorities, and because the least said about the fact that the Holborn sanitary authority, by refusing to pay the paltry sum of less than £15 per annum to three registrars, has deprived their medical officer of health of the use of these weekly returns, the better for the credit of the Holborn District Board. Holborn enjoys the unenviable notoriety of furnishing the largest contingent of fever cases to the Metropolitan Asylums Board fever hospitals, and can therefore ill afford to neglect any of those precautions which are deemed essential by other sanitary authorities and other medical officers of health. There appeared to us no necessity for medical officers of health to take part in the dispute between the Registrar-General and the sanitary authorities of the metropolis, but it might fairly have been expected that their interest would have been used in favour of the new system of returns, which renders them available for use on each Monday morning, instead of the old system under which they did not come to hand until Thursday morning. We are informed that some at least of the Holborn registrars have regularly furnished Dr. Gibbon with *gratuitous* information of cases of infectious diseases, but this is not acknowledged in his report.

We may take this opportunity of stating that Holborn is not the only metropolitan sanitary authority which still refuses to pay for these weekly mortality returns, and thus places their medical officers of health at a disadvantage in fighting zymotic disease, more especially during the present epidemic of scarlet fever. No weekly returns are yet furnished in St. George's (Hanover-square), Clerkenwell, Bethnal-green, Whitechapel, or Mile-end Old Town; we are, moreover, informed that in Shoreditch the vestry now demurs to pay for returns which the local registrars have been furnishing for more than six months under promise of payment. The other thirty-two of the thirty-nine vestries or district boards, constituting the metropolitan sanitary authorities, have long since made more or less satisfactory arrangements for the furnishing of these returns to their medical officers of health. We trust that the medical officers of health of the above-mentioned seven defaulting authorities will lose no opportunity to urge the inconvenience and danger to the public health arising from the neglect of this well-defined responsibility.

THE PRIVATE DISPENSARY SYSTEM.

This system was the subject of a very full and critical discussion at the meeting of the Islington Medical Society on Tuesday, held at the residence of N. H. Clifton, Esq., who presided. The interest in the question seemed the greater inasmuch as the system has had a considerable development in Islington. The universal feeling was that to pretend to doctor people for one shilling a week was to degrade the profession and to mislead, if not to defraud, the public. Some striking instances were given of the neglect of and imperfect examination of patients under such a system, such as a case of large pulmonary cavities and a case of urgent empyema, in which the chest had never been examined. Such cases seem to show, what one might *a priori* conclude, that private dispensaries are capital places for not having your diseases detected. Striking illustrations were also adduced showing the improper way in which the system was applied to those who can pay ordinary charges. One case was mentioned that used to receive treatment for a shilling a week, and afterwards came under the care of a regular practitioner, who was paid £15 for three months' attendance. It is only fair to add that the members generally expressed much interest in the difficult question of attending the poor medically and not charitably. Mr. Brown, of the Islington Provident Dispensary, expressed natural disappointment at the limited acceptance which such institutions had met with at the hands of the working classes. After ten years' existence, two medical men, who devoted three or four hours a day to the work, divided only about £100 a year between them in this institution. The discussion was adjourned to next meeting.

DR. WEBSTER.

A few weeks ago we announced that arrangements were being made by the inhabitants of Dulwich to erect a memorial to Dr. George Webster, who for the long period of sixty years resided amongst them, and we at the time gave expression to a hope that his honoured life might be yet spared to accomplish fresh deeds of usefulness and charity. It is with feelings of profound pain and regret that we now learn of his sudden death—struck down while apparently in the enjoyment of a vigorous old age, although it had already exceeded the period allotted by the Psalmist. On Saturday evening, the 12th inst., Dr. Webster entertained a few friends at his house, no one appearing in better health and spirits than the worthy host himself. On the following morning his servant found him lying senseless in his room with an apoplectic seizure. All that medical science, aided by assiduous love and care, could suggest proved unavailing. He never recovered consciousness, but passed away, bequeathing in his death a bright example and an unsullied name.

Dr. Webster was a Scotchman by birth, and came of a very ancient family in Forfarshire. At fifteen years of age he entered the University of Edinburgh as a medical student, and only three years later obtained the diploma of L.R.C.S. Young Webster immediately secured an appointment as army surgeon, and narrowly escaped being present with our troops at Waterloo. Peace stopped his career in this direction, and at the close of that memorable year (1815) he made his way to the village of Dulwich, and became a partner of Mr. Hall, the resident practitioner. Dulwich he never quitted. He found time amidst the cares of a large general practice to contribute several sound practical papers to the literature of medicine. Many of his professional brethren will remember him as the promoter of the British Medical Association, of which he was the first president.

He always displayed a keen interest in public affairs, and, in addition to being a prominent guardian and vestryman, was intimately associated with various institutions for the education and general amelioration of the youthful poor; notably he was well known as Chairman of the South Metropolitan Schools. In 1829 he obtained the M.D. Aberdeen. He was also F.R.G.S., and J.P. for the county of Surrey. The loss of Dr. Webster will be felt far and wide in the south of London, but by none more than by the poor.

ENTERIC FEVER AT CROYDON.

Eight deaths from enteric fever occurred at Croydon during the week ending Saturday, November 20th. These, with the deaths previously registered, make a total of eighty since the commencement of the epidemic. Last Friday a deputation of residents of Croydon, introduced by Mr. Grantham, M.P., waited on Mr. Sclater-Booth at Gwydyr House to ask for the appointment of an inspector to inquire into the causes that led to the outbreak. Dr. Chambers especially insisted on the necessity of at once ascertaining the causes of the present epidemic, so that an effective remedy might be applied without loss of time. No serious steps, he said, had been taken by the Local Board of Health to make the necessary investigations, and their measures had been confined as yet to frequent flushings and disinfecting of the sewers, in issuing instructions for domestic use, and commencing a house-to-house visitation. Mr. Sclater-Booth regretted he could not give a definite reply to their request. He had that morning received an elaborate report from the Local Board of Health at Croydon in answer to the official and authoritative inquiries made by his office. The report in question contained a document expressing, on the part of a number of gentlemen residing in the neighbourhood, perfect confidence in their medical officer, Dr. Philpot. In our article last week we bore testimony to that gentleman's valuable report, and fully endorsed the opinions expressed by him in it. We also urged the local authority to adopt without delay the chief recommendation it contained—to institute at once a searching inquiry into the immediate cause of the outbreak. This was the point urged by Dr. Chambers and the other members of the deputation upon Mr. Sclater-Booth, and we are anxious to learn what steps the local authority have taken to carry out the recommendation of their medical officer. Whatever may be the cause, it certainly is not due to any casual contamination of the water, but to some deeper and more extended sanitary defect. Last week we conjectured that this defect would most probably be found to lie in the faulty condition of the mains and sewers, and nothing has as yet transpired to make us alter the opinion we then expressed. Certainly the condition of the mains and sewers ought to be one of the first points to be inquired into.

BUYING AND SELLING PRACTICES.

There is nothing with which doctors are more frequently twitted than their differences, though it is doubtful whether they differ more than other men who have to deal with difficult questions. There is one thing, however, about which any two doctors are almost sure to differ. The thing we refer to is the value of a practice that has been sold; the two doctors are respectively the buyer and the seller of the practice transferred. As a rule they have the most diverse views on the question. The difference is likely to be still greater in the event of the seller removing to but a short distance from the place he is leaving. The particulars of a case in illustration are before us. They were elicited in the course of an action in equity in the County Court at Stone before the judge, W. Spooner, Esq. The plaintiff was Mr. Theodore Edgar Dickson Byrne, surgeon, of Newcastle-under-Lyne, and the defendant Mr. Daniel George Astley, surgeon, Beech Cliff, Trentham. Not unnaturally, the report of the trial is headed "Extraordinary Disagreement between Medical Men." We need not go into the details, as the case finally terminated in an amicable arrangement between the parties to the following effect:—"The agreement to be annulled. The defendant to return £100 in discharge of all claims and costs. Each party to be unlimited as to area of practice. All imputations to be withdrawn." We share with the judge satisfaction at the "happy conciliation attained." At the same time the case seems to point two morals: one, to purchasers, not to be too careless in investigating for themselves the real facts of a practice—in legal language, *caveat emptor;* the other to sellers, not to colour too highly the representations of the value of the practice to be sold. It is, to say the least, an undignified thing to have one's own witness in such a case admit that the average value of midwifery cases was overstated, and to have, as a result of the conciliatory arrangement, to return part of the payment. It is reasonable that men who have created practices should sell them when they see fit to do so; but the terms and the representations should be so conspicuously just as to make a complaint in the law courts hopeless.

WARMED RAILWAY CARRIAGES.

Among the diseases easily preventable by better social contrivances must certainly be reckoned a large number of those which result from the external application of cold. How many lives might be saved every winter had we better organised arrangements for the protection of invalids from cold during travelling! The discomfort of railway journeys at this time of the year is not only annoying, but to many the exposure is a source of positive harm. Hot-water tins are the only means of maintaining the temperature, and they can act only on a small part of the body, and scarcely at all on the air respired. On many lines of railway, even, as appeared from a letter to a contemporary, on some main lines which derive so large an income from the conveyance of invalids as the South Western, hot-water tins are not always to be obtained even at a terminus. On some parts of the Continent the arrangements for warming the carriages are much more efficient. The composition of the train, consisting of saloon carriages connected with one another, renders it possible to heat them properly and pleasantly with warm air, and thus a journey in mid-winter is robbed of half its discomfort and danger. Such a system would probably not be practicable with our present small compartments. It would be impossible to regulate the temperature and fresh air in an efficient manner, and an alternation of baking heat and freezing draught would be the only result. But the need for warmed carriages is very great, and should constitute another motive for the supply of better constructed railway carriages in which such safe and effective warmth might be possible.

THE HEALTH OF ETON.

The answer the Rev. Charles Wooley Dod was able to give in *The Times* last Monday to the letter of "A Father" on the health of Eton, which appeared the preceding Saturday, must be considered eminently satisfactory; and there can be no doubt that the uneasy feeling excited by the ill-advised communication in question has been allayed by Mr. Dod's straightforward statement. Our Sanitary Commission have had occasion to visit Eton twice within the last eighteen months; on the first to report on the new system of sewerage and drainage which had recently been completed, and on the second to collect materials for our Reports on the Sanitary Condition of our Public Schools. On both occasions the drainage question was a subject of particular inquiry, and we are pleased to be able to state that the system adopted is working well, and that there is no possibility of the sewage being choked back by the floods or otherwise. Eton, from its low-lying situation, has always been subject to floods. In 1852, as we are informed by Mr. Dod, the water rose eight feet six inches above the ordinary summer level—the highest flood recorded for forty years; since that time recent arterial works on the Thames have reduced the flood level nearly two feet, a most important fact with reference to the drainage of towns in or near the Thames valley. In this year of extraordinary floods, the highest level reached has been seven feet nine inches, or seven inches below the highest flood level recorded for forty years. If typhoid fever should be introduced into Eton, the possibility of its spreading would not be through the medium of the sewers, but by the water-supply. The chance of the water-supply becoming contaminated, however, has been reduced to a minimum since the old cesspools have been done away. There are many points of detail no doubt connected with the sanitary arrangements of the school that call for improvement, as is the case in nearly every school we have yet visited, but the authorities must be acquitted of the charge of neglect and indifference to sanitary matters; the fact that an extensive drainage scheme on the separate system has been satisfactorily carried out is a proof to the contrary. To place Eton in the same category as Uppingham shows the profoundest ignorance of the first principles of sanitary science.

IMMUNITY FROM SMALL-POX IN LONDON.

In his last Weekly Return the Registrar-General calls attention to the recent remarkable immunity from fatal cases of small-pox which has been enjoyed by the 3,445,160 persons now estimated to be residing within registration London. It appears that since the week ending July 17th last, more than four months, no death in London has been referred to small-pox, whereas the corrected average number in the corresponding period of eighteen weeks in the ten years 1865–74 was no less than 337. This period, however, includes the remarkable epidemic of 1871-2. Since the beginning of the year 47 deaths from small-pox have been registered in London, of which 31 occurred in the first and 15 in the second quarters of the year, and the last case, as before mentioned, during the week ending July 17th. Since this date the 16 deaths which have been attributed to small-pox in London in the Registrar-General's Weekly Return have all been fatal cases of varicella or chicken-pox. The last Quarterly Return of the Registrar-General showed that the fatality of small-pox was unprecedentedly low throughout England and Wales during the three months ending September, and the remarkable freedom from a fatal case in London during more than four months is certainly without precedent since civil registration was established in 1837. It will be somewhat interesting to observe how these facts will be twisted by the ingenuity of the anti-vaccination leaders to support their case against compulsory vaccination.

THE KEIGHLEY GUARDIANS AND THE MANDAMUS.

The guardians of the Keighley Union are making a very sorry and ridiculous exhibition of themselves before the country. They have prepared and forwarded the following return to the writ of *mandamus* issued against them by the Court of Queen's Bench:—

> "We, the guardians of the Keighley Union, to whom this writ is directed, do most humbly certify and return to our Sovereign Lady the Queen—1st. That the said writ cannot be obeyed without serious damage to the health of the inhabitants of the Keighley vaccination district of the Keighley Union, and without increasing mortality among young children; it being the fact that, notwithstanding the adoption of all modern sanitary improvements, infant death has been increased by enforcing the Vaccination Act in large towns. 2nd. That the Local Government Board have power to direct the vaccination officers to prosecute persons omitting to obey the Vaccination Acts; consequently, it is not necessary to require the guardians to do so. Under the circumstances herein appearing, they humbly submit that they ought not to be compelled to do so."

We will leave the Court of Queen's Bench to say what is the force of this answer regarded from a legal point of view. As we have already said, the interest of the case between the guardians and the Court largely supersedes the interest of the abstract question of the wisdom or otherwise of compulsory vaccination. We will only say that, from a medical point of view, the main part of the answer is as erroneous as it can be. If a reasonable time be taken into account, it will appear that the application of the compulsory Vaccination Acts has immensely reduced the mortality of young children. Small-pox occurring in unvaccinated children kills 40 or 50 per cent. of them; whereas few practitioners could be found who have seen such a thing as a child's death from vaccination, either direct or remotely.

It is only proper to say that the above answer to the *mandamus* was the work of only six guardians, four others present opposing it. Amongst the dissentients, Mr. Redman deserves praise for the words of sense which he spoke. He very forcibly referred to the snubbing which the Keighley guardians have received from other boards. Not content with not obeying the law themselves, they have tried to incite other boards to disobedience; and they seem signally to have failed. At the end of the same meeting at which the return to the *mandamus* was settled, answers to the overtures of the Keighley guardians from three boards were read, which may be taken as specimens of others. The Hexham Union stated that they could not concur with the Keighley guardians in presenting a petition for the abolition of vaccination. Romley Marsh Union declined to interfere. The Leicester guardians had resolved, "That this board, having no sympathy with the views expressed in the memorial of the Keighley guardians, declines to take any part in supporting them in their resistance of the law."

It is to be hoped that the Keighley guardians will begin to see that they are not taken for great lights by other boards, and the sooner they exchange the work of teaching for that of learning the better it will be for their reputation.

CHLORAL.

The uncertainty of the action of chloral, however rare, is an undoubted fact which lessens very much the safety of the drug. Some time ago we expressed the opinion that unexplained death after chloral was more common than after any other of the narcotics in common use. Two cases reported in the daily papers since our last issue afford fresh support to this belief. In one case a medical assistant, on whom an inquest was held at University College Hospital, was in the habit of taking hydrate of chloral to induce sleep. He was found in the street dying, as if from the influence of some narcotic poison, and when brought to the hospital was actually dead. In the other case a lady, said to have been subject to epileptic fits, had a small dose of chloral (ten grains) administered to her, and was found the next morning lying on her face, and dead. Death after an epileptic fit from accidental suffocation is not uncommon, and it is very possible that it was in this way that it happened. But if a fit occurred during the night it does not appear to have been sufficient to rouse the husband of the lady who was sleeping by her. The habitual dose of chloral cannot be acquitted (in the absence of any direct evidence of a fit) of having contributed to the fatal result. Each case points the lesson very strongly that the nocturnal use of chloral is not without its dangers, and should, as much as possible, be discouraged.

DR. WARD.

We regret to have to announce the decease of Dr. S. M. Ward, of Chobham, which took place on the 16th instant. He was the youngest son of the Rev. Canon Ward, formerly Rector of Meesden, Hertfordshire; was educated at Tunbridge School, whence he proceeded to Caius College, Cambridge, in 1854, having obtained a Tancred Studentship in Medicine. He graduated as B.A. in 1858, and afterwards as M.B., having previously been elected a Scholar of his College. He completed his medical education at St. Bartholomew's Hospital, and succeeded to the practice of the late John Langdon, Esq. Dr. Ward was an accomplished physician, and successfully worked a very large practice, which embraced nearly all grades of society, from the highest to the lowest. The Poor-law appointment which he held brought him in daily contact with the poorer population of his district, with whom he had endeared himself by his kindly and generous qualities. These must feel his loss acutely. Dr. Ward leaves a widow and eight children.

REPRESENTATION UNDER THE ARTISANS' DWELLINGS ACT IN BRISTOL.

Last week we urged that the recent excessive fatality of scarlet fever in certain of the crowded portions of the city of Bristol, in which high death-rates generally prevail, could not safely be disregarded as evidence that the city contains "unhealthy areas" which should be dealt with under the Artisans' Dwellings Act. On the same day that we went to press a meeting of the Sanitary Committee of the Bristol Town Council was held, to receive an important representation from Mr. David Davies, their medical officer of health, describing "all the area subject to inundations of the river Froom, lying within the city of Bristol, as an unhealthy area, and all the houses within such area as permanently unfit for human habitation until such means have been adopted as to preclude any inundation of such area by the waters of the river Froom." This is undoubtedly a bold and novel application of the powers conferred upon medical officers of health and local sanitary authorities by the Artisans' Dwellings Act, but if the facts asserted by Mr. David Davies in his report are substantiated by further investigation, we cannot see what is to prevent the provisions of the Act from being put in force to redress a great evil. Hitherto it has only been sought to apply the Act to clear away, by means of an improvement scheme, the crowded and squalid courts and alleys of our large towns. This considerable area in Bristol, though covered with new houses, is not only continually subject to floods, but the houses and drains are constructed of bricks that can be crumbled between the fingers. Some of the houses are, moreover, so unsound that the walls are only kept from falling by iron straps. This revelation is a singular commentary upon the nature of the local bye-laws relating to building in Bristol, or upon the way in which they are carried out. It was decided that a special meeting of the committee, to consider the representation of their medical officer, should be held as soon as sufficient information had been obtained to enable them to arrive at a decision. A strong *prima facie* case has in the meantime been established that the houses on this area are "unfit for habitation" within the meaning of the Artisans' Dwellings Act.

A RECENT INQUEST.

Our attention has been directed to the report of an inquest held at Lowestoft by the deputy coroner of the district, which affords a very good proof, if any were wanting, that none but properly qualified (in the broadest sense) medical men should hold the office of coroner. The facts are briefly as follows. A fine healthy infant of fifty-two days old gets eight drops of "Godfrey's cordial," is soon after suckled by its mother, and shortly after this vomits and dies in about four hours. The eight drops of the cordial were administered to the infant at 11 P.M. The child slept in the same bed as the parents; the mother took the child into bed with her, and all soon fell asleep. About 10 minutes to 3 A.M. the father was awakened by his wife, and discovered the infant dead by its mother's side. The child had always slept on the mother's arm, but on the night in question her arm was above it. The bottle containing the remainder of the drops was produced at the inquest. The chemist who both made and supplied the "cordial," and was responsible for the doses named on the label of the bottle, gave evidence as to the ingredients of which it was composed, and swore that it contained exactly one minim of tincture of opium in thirty-two minims of the "cordial." The evidence, as we have said, gives eight drops as the dose taken. This will equal one-fourth of a drop of laudanum, or about one fifty-sixth of a grain of opium. The druggist declared in his evidence that he sold one hundred pennyworths of the cordial in a week, and that he had never known a fatal case to arise from using it. Dr. Ringland, who had been called in to see the infant, attributed its death, without the slightest doubt, to an overdose of opium; and, in reply to a question from a juror as to how this opinion could be reconciled with the fact that the druggist had for years sold upwards of one hundred pennyworths of the cordial without the occurrence of a fatal case, stated that the very healthiness of the child in question would make the administration of opium to it the more dangerous. The jury returned a verdict in accordance with the coroner's charge—viz., that the child died from an overdose of opium ignorantly administered, and the coroner, after expressing his concurrence with that verdict and passing an encomium on Dr. Ringland for his excellent evidence, declared that if a death should result from such causes in future, he should be under the painful necessity of directing the jury to return a verdict of manslaughter.

It is almost a platitude to say that the administration of opium to infants of tender age requires extreme care, and should certainly only be done under the advice of some medical man after having seen the case. The use of opiates for infants under the name of Godfrey's Cordial, or in any other form, is unquestionably a very reprehensible practice, and we are utterly opposed to chemists and druggists taking upon themselves the very grave responsibility of prescribing such things on the application of parents for something to quiet a child. But what we have now to consider is the evidence and the verdict in this particular case. It seems to us far more probable that the death of the infant was caused by asphyxia from an overdose of the parents than from an overdose of opium. The infant was most probably suffocated by what is commonly termed being overlaid. While fully recognising the susceptibility of infants to the action of opium, yet the dose in this instance, according to the sworn testimony of the witnesses, was so minute—one-fourth of a drop of tincture of opium—that we cannot help thinking a coroner, if himself acquainted with the purely medical aspect of the question, would, at any rate, have striven to exclude all other causes of death before attributing it to the one in question.

ENTERIC FEVER ON BOARD THE "CORNWALL" SCHOOL-SHIP.

As mild cases of typhoid fever still continue to appear among the boys on this ship, and several relapses, a large steamboat was procured, and all the healthy boys were transferred to her on Saturday last. This vessel was sent down the river, and is now moored below Gravesend, near the hospital-ship *Rhin*. All the sick and convalescents are on board the latter vessel, and since this complete removal no cases have occurred. A thorough examination of the ship has been made, and it is probable that she will undergo a further inspection in dry dock. The question of moving the ship to another position in the Thames is still undecided.

SANITARY NOTES.

The solicitor of the Board of Trade conducted a prosecution on the 17th instant against the master of the ship *Sarah Smeed*, the charges being that no lime-juice was given out during the entire voyage to and from Lagos, and that no entry of illness of any of the crew was made in the official log. Several of the crew were seriously ill with West Coast fever, and one had also marked symptoms of scurvy, which appears to have exaggerated the ill effects of a wound of the leg, for which he is still under treatment at the Seamen's Hospital. Both offences were proved, and the legal penalties inflicted by the presiding magistrate. This is the second prosecution conducted by the Board of Trade during the past month on account of scurvy and neglect of those clauses of the Merchant Shipping Act that relate to health of crews.

Mr. Ebenezer Davies, medical officer of health for the Port of Swansea, gives some interesting particulars as to work done during the past year, and records a glaring instance showing the necessity for port sanitary surveillance in view of preventing the spread of epidemic diseases. But the observations made as to cholera are altogether beside the question, as indicating a return to the old and useless restrictions of quarantine. If Mr. Davies will read carefully the order in Council of July 17th, 1873, with reference to cholera, he will find that, if properly administered, it affords a very sufficient provision against the importation of the disease.

THE HEALTH OF THE WAR MINISTER.

There is nothing like improving the occasion; and one of our provincial contemporaries, seeing, we presume, that Mr. Gathorne Hardy's name had been conspicuous for its absence from some cabinet meetings, and learning that the right honourable gentleman was ill, was neither at a loss for a name for the disease nor for the cause to which it might be attributed. Mr. Hardy was suffering from "War Office fever," and added another name to the list of officials who had been "knocked over" and obliged to absent themselves from that unhealthy building. The atmosphere of the War Office, by all accounts, is not that of a summer garden; but as Mr. Gathorne Hardy's late indisposition was ascribed to that common complaint a "cold in the head," we may acquit the War Office this time, and lay the charge to the weather. Any War Office fever from which Mr. Hardy may have been suffering was probably of another kind altogether, arising from the intricate and tangled mass of work before him. This was, no doubt, well calculated to induce lowness of spirits in the most Mark Tapley type of character. However, it will be gratifying to an army all anxious to see "what he will do with it" to be assured that the War Minister is very nearly "himself again," and will, we hope, shortly take his accustomed part at Cabinet Councils.

A SLIGHT DIFFERENCE.

Touching some recent statistics of our contemporary, the *World*, as to the risks encountered by Europeans in India of contracting and perishing from cholera, it will be remembered that it was computed that there was one death out of thirty-seven Europeans attacked with that disease. Those acquainted with the terrible nature of the disease naturally raised the "eyebrows of astonishment" when they found it had been robbed of nearly all its terrors, and was, after all, a very mild kind of disease. Dr. Bryden's tables unfortunately tell a very different story, however. From these we learn that among European and native troops occupying the same stations during the invading epidemics of late years, the mortality of those treated for cholera has averaged 60·19 per cent. for the European and 43·02 per cent. for the native troops.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

On the 20th inst. an election took place for a Vice-President of this College in the room of the late Mr. Hamilton, when Dr. George H. Kidd was appointed without opposition. A vacancy having occurred in the Council, three candidates competed—viz., John Cronyn, Thomas Darby, and Robert Persse White. The first two gentlemen each polled forty-two votes, the casting vote being given by the president in favour of Mr. Cronyn, who was thereby elected.

THE PUBLIC HEALTH OF ST. PETERSBURG.

A Russian sanitary periodical, aptly and briefly entitled *Health*, publishes some statistics which conclusively demonstrate the unwholesome condition of St. Petersburg. Cholera, it is true, has not made its appearance this year, but a typhoid epidemic has continued its ravages notwithstanding the magnificent summer recently enjoyed on the banks of the Neva. With the advent of winter, the number of deaths has risen to nearly double the average chronicled during the summer months. This fatal increase is, however, the ordinary consequence of the rigorous climate, and will not be reduced again till the end of April, but the rate of mortality is higher than it should be all the year round, and this may be attributed to inadequate sanitary precautions, though the fact is not generally realised. The number of inhabitants has multiplied so rapidly that at first sight many persons might believe the increase of population to be a result simply of natural causes. M. Yélatchitch, secretary of the St. Petersburg Statistical Committee, has, however, issued a publication which clearly proves that this augmentation in the number of citizens is due to immigration, and not to the excess of births over deaths. When St. Petersburg was founded there were about 25,000 inhabitants gathered within its walls during the first few years of its existence. Subsequently, in 1750, the number rose to about 80,000. The first census was taken in 1764, and it estimates the population at 192,000. This number increased to 220,000 in 1800, 308,000 in 1812, 470,000 in 1840, and 522,000 in 1863. On the other hand, we find that the average annual number of births from 1764 to 1770 was 5122, while the deaths during the same period amounted to 4677; but from 1808 to 1813 we note a great change, for there were nearly 6000 more deaths than births during that period. Again, in 1848 no less than 31,707 deaths were registered, to correspond with 14,529 births. Altogether, and taking the whole century, there have been 1,095,451 deaths, and only 962,689 births, in St. Petersburg.

DECLINE OF THE SCARLET FEVER EPIDEMIC.

True to the experience of previous epidemics, the fatal cases of scarlet fever showed a marked decline on the first appearance of winter temperature. In the eighteen large English towns furnishing weekly returns, and having an estimated population of nearly six millions and three-quarters, the deaths referred to scarlet fever in the third week of this month fell to 185, from 231 and 260 in the two preceding weeks. In London, the numbers in the three weeks ending the 20th inst. were successively 129, 116, and 96; and, excepting an increase in Nottingham and Salford, the fatality of the disease showed last week a general decline in all the large towns. The annual death-rate from the disease in the week ending 20th inst. was, however, equal to 1·5 per 1000 in London, 2·8 in Bradford, 3·5 in Salford, 4·3 in Bristol, and 4·5 in Nottingham.

SIR TREVOR LAWRENCE.

We are glad to be able to announce the unopposed return of Sir J. J. Trevor Lawrence as the parliamentary representative of Mid-Surrey. As we have before stated, the new senator is a member of the medical profession, and formerly served his country in the medical department of the Indian Army. He was born in 1831, and in 1867 succeeded to the title, by the death of his father, Sir William Lawrence, F.R.S., Serjeant-Surgeon to the Queen. The small band of doctors in the House of Commons have received a welcome accession to their number. There are great questions now coming on before Parliament which cannot be properly discussed without the aid of medical men and sanitarians.

A HEALTHY YEAR IN INDIA.

Dr. J. M. Cuningham, the Sanitary Commissioner with the Government of India, reports that the sanitary history of 1873 presented a very marked contrast to that of 1872. In some parts of India small-pox was epidemic, and had caused much mortality among the people during several months; generally there was a remarkable absence of cholera, and a considerable diminution of other diseases compared with other years; cholera can only be said to have been epidemic over a small area, while its dormancy over certain large tracts of country and its almost complete absence from others had been very striking features. These remarks are borne out by the statistics of the European troops, who appear to have suffered little from any serious epidemic, and the year, as a whole, was an unusually healthy one.

UPPINGHAM SCHOOL.

We are requested by Mr. Haviland, who is investigating the recent outbreak of enteric fever at the Uppingham School, to say that he will be much assisted in his inquiries if the medical attendants upon boys who have fallen ill shortly after leaving that school will kindly favour him with notes of the facts of illness and particularly of the date of the commencement of illness. Letters should be addressed to him at Northampton.

We gather from a report of the sanitary condition of York, recently issued by Mr. S. W. North, that the health of the city is by no means good. The death-rate during the last quarter has been unusually high, and there was a great deal of sickness from diseases of the zymotic class. Many cases of enteric fever were reported, and on investigation it was ascertained that the sewerage and drainage of the localities of the outbreaks were defective. New sewers are now in course of construction, and other improvements are being carried out, which cannot fail to have a beneficial influence on the health and comfort of the inhabitants.

A brief report of the health of Hastings during the last quarter has just been issued by Mr. C. Ashenden, medical officer of health. The death-rate during the period was 18 per 1000 annually, which is rather a higher figure than could be desired for a town with such great natural advantages. The borough was free from epidemics, although cases of zymotic disease were imported into the town. Mr. Ashenden thanks the urban sanitary authority for having provided a disinfecting apparatus and for sanctioning his appeal for a hospital for infectious diseases.

Last week Dr. Inglis, late of Worcester and now of Cheltenham, was presented by the inhabitants of the former city with a testimonial in the form of a silver salver and a vase containing one hundred guineas. The salver bore the following inscription:—"Presented to Dr. Inglis, with a purse of gold, on the occasion of his leaving Worcester, by his numerous friends, as a token of esteem, and in recognition of his valued services to the Infirmary and Dispensary: November, 1875." We heartily congratulate Dr. Inglis upon this expression of goodwill and of appreciation of his work in Worcester.

The supply of subjects to the schools this session is so much less than usual that complaints are almost universal among the teachers of anatomy. In many schools the number of bodies which have been received is only one-half of that which they had at a corresponding date last year, and we much fear that the influence of this diminished supply will be greatly felt at the January examinations.

Dr. Charles Warden has resigned the office of senior honorary surgeon to the Birmingham Lying-in-Charity, having been associated with it for nearly a quarter of a century in its present form, and as the Lying-in Hospital for Midwifery and the Treatment of Diseases of Women and Children. The General and Medical Committees passed resolutions highly complimentary to Dr. Warden as to his valuable services, and expressive of much regret at losing them.

A meeting of the Society of Medical Officers of Health was held on Saturday last, when an interesting paper on Sanitary Administration in India was read by Mr. W. R. Cornish, sanitary commissioner in Madras. The discussion was introduced by Dr. Druitt, who has recently returned from India, and some pertinent observations on the subject were made by the President and Dr. Letheby.

We understand from a Calcutta newspaper that, in compliance with orders recently issued by the Government of India, the arrangements and equipments for the Prince of Wales's staff have been created into a special department, a portion of which will accompany His Royal Highness during his tour. The European and native apothecaries who attended on the Duke of Edinburgh during his visit to India have been appointed to the new medical establishment.

A case which illustrates the need that exists for the obtainment of a higher class of attendants on the sick in some of our public charities came before the Salford Borough Police-court a few days ago. Two nurses employed in the small-pox and fever wards of the Salford Workhouse were sentenced to twenty-one days' imprisonment for drunkenness, and it was stated that during their debauch they left thirteen or fourteen patients entrusted to them quite unattended.

We are glad to be enabled to announce that Sir John Glover is progressing favourably towards recovery under the professional treatment of Mr. R. G. Butcher, of Dublin.

Mr. William Colles, Regius Professor of Surgery in the University of Dublin, has been appointed Surgeon in Ordinary to Her Majesty in the room of the late Mr. Hamilton.

REPORT
OF
The Lancet Commission
ON THE
SANITARY CONDITION OF OUR PUBLIC SCHOOLS.

◆

ROYAL MEDICAL COLLEGE, EPSOM.

We have so frequently advocated the claims of the Royal Medical College that we feel no special introduction is needed on this occasion to explain the aims and objects of the institution. The College is situated on the north-west slope of the Epsom Downs, about one mile from and eighty feet above the town of Epsom. The buildings consist of a main block, which contains the dining hall, the dormitories, and the school and class rooms; attached to this block is the "Albert Memorial Wing," set aside for the residence of the pensioners. At the southern extremity of the main building is a residence for the head master, with accommodation for forty boarders; this house was presented to the College by the munificence of Mr. Erasmus Wilson. The out-buildings in the back playground consist of a gymnasium, two swimming-baths, a lavatory, and a range of closets and urinals; all these are closely connected with the main building. In the large front playground is a fives-court and the chapel. All the principal buildings are of red brick, faced with freestone, and are well and substantially constructed; they rest directly on the chalk. The aspects are north-west and south-east, the latter being sheltered by the down that rises behind the College. At the present time there are residing at the College 50 foundation scholars, who receive their education free; 165 resident pupils, paying, if the sons of medical men, from £48 to £51 a year, or, if not the sons of medical men, £70; and 24 pensioners, each of whom has a set of chambers allotted, and receives, besides, certain other privileges. In addition to these must be reckoned the tutorial staff, the servants connected with the institution, and the servants and relatives living with the pensioners,—making in all a population of about 300.

Drainage and water-supply.—Formerly the drainage of the College was received into large cesspools, situated at the north-west extremity of the College grounds. This arrangement was found to be so extremely unsatisfactory that it was determined to make a junction with the town system of sewage. This has been effected at a cost to the College of £400. The College drainage now consists of two sewers; the principal one on the high level, which is connected with the main block, and passes behind the buildings to the end of the Albert wing, and then, turning downwards, makes a junction with the smaller sewer, which comes from the master's house, about fifteen yards from the lodge gates, where the town system may be said to commence. The ventilation of the College drains is effected by three untrapped water-pipes, which are placed at points of the buildings where there can be no possibility of sewer gas escaping from them into the building; in addition, at the back of the school, at the commencement of the high-level drain, is a man-hole with an open grating. We do not think the ventilation provided sufficient, considering the College stands eighty feet above the level of the town, and the pressure consequently in the upper part of the sewers must be very great. We should therefore recommend that increased ventilation be effected at the junction of the College and town drains, so that all possibility of the town gases making their way to the building may be prevented. The substitution of an open grating for the present closed cover of the man-hole, in this situation, would doubtless be sufficient; but a ventilating shaft would be more effectual, and perhaps safer. The water supplied to the College is furnished by the Epsom Town Waterworks. The supply is supposed to be constant; but, owing to the scarcity of water, the mains are often empty for some hours, and an insufficient quantity furnished to the school. In order to keep an adequate supply on the premises, a large open tank has been built on the top of the central tower, in which a considerable quantity of water is stored. For some time past complaints have been made that the water when drawn (generally the water first taken in the morning) has been thick and turbid, yielding a rusty deposit. This condition of water has been noticed only in the supply of the main building; and the Albert wing that furnishes the master's house, though taken from the same point in the town mains, has hitherto been free from deposit. This points to some local defect in the service of the main buildings, certainly not to any general contamination of the water-supply itself. Mr. Elkington, the architect of the College, has offered, we think, a very reasonable explanation of the cause of the deposit, and, though it is difficult to speak positively till the necessary examination be made, we venture to predict it will be found correct. It appears the main, on entering the building, gives off two lateral branches for the wings; these ascend slightly before their ultimate distribution. Mr. Elkington thinks that these have become corroded, and that the rust from these is sucked up during the periods of intermittency into the pipes connected with the whole service. The fact that the water is foulest in the morning gives additional support to this view, since the intermission, when it occurs, is usually during the night time. In all other respects we were satisfied with the purity and quality of the water supplied, and we were glad to see that the additional precaution had been taken of having Lipscombe filters attached to all taps and cisterns from which water for drinking purposes could be obtained. We think, however, the Council ought to insist on the town water-supply being made constant without delay, for till that is done there is danger at any moment of typhoid being introduced into the school from the town; the experience of Over Darwen, Lewes, and Croydon ought not to be disregarded. If the Council fail in obtaining a constant service, they should, we think, endeavour to obtain a water-supply of their own. They have on their premises a well, sunk in the chalk, about 130 feet deep, yielding an abundant supply, and if this on analysis prove as good as it is abundant we think that, under any circumstances, they would be wise to employ it. The cistern at the top of the tower ought also to be covered in; at present it is exposed to large quantities of smoke and soot from the chimneys close to it.

General sanitary details. — The halls, school and class rooms, dining-hall, and dormitories are all lofty and well-lighted, but we cannot say well ventilated. Certainly plenty of fresh air enters the buildings, but, to judge by the draughts, it passes in with too great velocity and is irregularly distributed. We can fully understand the complaints that have been made with respect to the cold and draughty corridors, and we hope the Council will do something to remedy this evil before next term begins. The introduction of two or three Galton stoves in each corridor would materially warm the air of the building and improve the ventilation by equalising the currents of air. The school and class rooms are excellent, and, for the accommodation afforded, may compare with any school in the kingdom. In the large school-room and in several of the classrooms, a rearrangement, however, of the seats would be advisable, so that the shadow of the boy may fall to the right or left of him, and not on his book or copy. The school is provided with two excellent swimming baths, one hot, the other cold, and also a gymnasium; indeed, we cannot speak too highly of the liberality of the Council in providing for the general comfort and convenience of the boys. In the back playground, near the school-rooms, is a range of privies and urinals; the former have an arrangement for flushing, which is done once a day at least, and is very effective. The urinals are of slate, with an iron-pipe arrangement for flushing. As usual, when the water was turned on we found that, instead of a good strong stream, only ineffectual little dribblets trickled down the slabs. The only efficient method we have seen for keeping urinals clean is a simple but extremely powerful tap facing towards the urinal: this should be turned on twice a day. In the back playground is a tap to which the boys have access, all the water supplied having passed through a Lipscombe's filter. All waste and overflow pipes are disconnected from the sewers, and are discharged over well-trapped gratings. Where possible, the rain-water pipes have been disconnected; we should like to see this plan adopted with all, and the rain-pipes at present used for ventilating the drains changed for proper ventilating shafts. We were pleased to see that some attempt had been made to utilise the rain-water by collecting it in cisterns in different parts of the buildings; if our suggestion of cutting off the remaining connected rain-pipes be carried out, the soft-water supply of the College would, if stored, be greatly increased. The closets in the College are fitted with separate cisterns; none that we saw had screw taps, and the architect distinctly assured us that no such taps were used in the building.

The precautions employed to prevent the introduction and spread of infectious disease.—On returning to school, each pupil is expected to bring with him a certificate that he is in good health, and has not been exposed within one month to any disease of an infectious character. In the head master's house a general statement is required in addition, on entrance, with respect to the general state of health and the infectious diseases he has had. The medical officers of the school (Dr. Jones and Dr. Barnes) this term, on their own responsibility, examined every boy on his return to school, and in future a record of the boy's height, weight, physical development, and illnesses is to be kept, the examination to be made every half-year on the boy's return from home. We think the Council ought officially to acknowledge the additional and valuable labour thus voluntarily undertaken by their medical staff, and that the "Health Register" should become a recognised feature in the management of our "Medical College." It is a rule for all boys that fall out of school to be seen by the medical man at his next visit; we would suggest, as an extra precaution, that the patient should be isolated in a sick room, however trivial the complaint, till the visit had been made. The great want at Epsom hitherto has been a sanatorium for the isolation of infectious cases. A building for this purpose is now to be erected, affording accommodation for twenty-four patients, and the site selected, though somewhat near the Albert wing, is as far as possible from the school itself. At the end of the last term, and the beginning of this, scarlet fever made its appearance in the school; the first outbreak was limited to seven cases, the last to five. We are fully satisfied with the arrangements made by the medical officers of the school for the accommodation and isolation of the cases at present under treatment; the fact that the epidemic has not spread shows how effective those measures have been.

General remarks on the school hours, work, meals, &c.—School commences at 7 o'clock in the morning; at 8 the boys go to breakfast; at 9 to chapel; at 9 30 the boys go to work again till 12.30; at 12.45 the first dinner to half the school, and at 1.45 the second dinner for the remaining half is served. School reassembles at 3.30, and continues till 5.30; then chapel at 6, and tea at 6.30. School again at 7, lasting till 10, with a quarter of an hour allowed for supper. These hours give a daily total for work of eight hours and three-quarters on whole school days, and six hours and three-quarters on the two half-holidays. We consider these hours to be in excess of what they should be. The time of work at our great public schools generally averages but seven hours on whole school days; whilst on half-holidays, which at many schools are every other day, the work is from four to five hours. We are aware that at Epsom few of the boys are intended for a university career, and that they are chiefly trained with a view of becoming candidates in the competitive Civil Service Examinations, or for the severe Matriculation Examination at the University of London—examinations which require a considerable range of subjects to be taken in hand. Still, eight hours and three-quarters' work is a very severe strain on boys of twelve or fourteen, and should only be imposed on the older boys, and those who are preparing for an immediate examination. We would venture to suggest that afternoon school should not commence till 4.30 and continue till 6, and no work should be done by boys under fourteen after 8 30. This would reduce the number of working hours for juniors to seven a day, and for seniors to eight; moreover, this arrangement would give the boys an extra hour for afternoon play. The meals are four in number: breakfast at 8, of bread-and-butter; a substantial meat meal at the midday dinner; tea at 6.30, of bread-and-butter; supper at 9, with bread and cheese. We think these meals are sufficient, and we do not consider an extra meat meal necessary. Complaints have reached us that sufficient time is not allowed the boys at dinner, especially at the second meal. This, we fancy, must be their own fault, in their desire to get to the playground. If such is the case it could be easily remedied by insisting on the boys remaining in hall at least half an hour, and allowing none to leave till that time has expired.

In conclusion, we must bear testimony to the excellence of the domestic arrangements and the care and nicety with which the food is prepared. No one can visit the Royal Medical College without feeling impressed with the great and noble work that is being carried on, and how unwearied must have been the efforts of all connected with the establishment to bring it to its present perfection. Apart from the merely charitable aspect of the institution, it is a fact of no mean significance that nearly two hundred boys are receiving an education almost equal in some, and vastly superior in other, respects to that given by our large and expensive public schools, at a cost to the parents of barely £50 a boy. The Council, in building the new sanatorium, will be put to considerable expense. We hope the members of the profession and the public will continue to give them liberal support, for without that it is impossible for any of the suggested improvements to be carried out.

ANSTIE MEMORIAL FUND.

A MEETING of the General Committee of the Anstie Memorial Fund will be held on Tuesday, the 30th of November, at the House of Dr. George Johnson, 11, Savile-row, at 8.30 P.M. precisely. The following report of the Executive Committee will be presented, and resolutions embodying its recommendations will be proposed for adoption:—

The Executive Committee of the Anstie Memorial Fund beg leave to report to the General Committee that the accounts of the Fund were closed on the last day of February, although a few contributions have since been received. The total amount collected was £2548 8*s.*, and the total expenses of the collection were £153 8*s.* 4*d.* Of this amount the sum of £50 was defrayed by a single donation given for this especial purpose, so that only £103 8*s.* 4*d.* will rank against the fund, leaving a balance of £2444 19*s.* 8*d.* available for the purposes for which it was collected. On this balance dividends to the amount of £60 19*s.* 10*d.* have been received, making a total sum of £2505 19*s.* 6*d.*

The purposes of the fund, as defined by the original circular issued by the Executive Committee, were to set up a memorial tablet in some proper situation, and to devote the remainder to the education or advancement in life of Dr. Anstie's children.

The Chapel of King's College naturally suggested itself as the best place for the proposed tablet; and Sir Gilbert Scott kindly undertook to furnish a design in harmony with the decorations of the interior. A considerable time elapsed before this design was prepared, and then an inscription which was approved by the Executive Committee was found not to be acceptable to the Council of King's College. Further delay and much correspondence were thus occasioned; but ultimately the following inscription, which was written by Mr. John Simon, F.R.S., removed all difficulties:—

In Memory of
FRANCIS EDMUND ANSTIE,
M.D. LOND., F.R.C.P.,
PHYSICIAN TO THE WESTMINSTER HOSPITAL,
HONORARY FELLOW OF THIS COLLEGE.
LABORIOUS IN STUDY, ACCOMPLISHED IN PRACTICE,
ARDENT IN LOVE OF TRUTH AND JUSTICE,
STRENUOUS IN EFFORTS FOR THE POOR AND FRIENDLESS,
HE WAS STEADFAST, GENTLE, AND AFFECTIONATE
IN ALL PERSONAL RELATIONS,
AND DEAREST TO THOSE WHO KNEW HIM BEST.
HIS DEATH, WHICH TOOK PLACE ON SEPTEMBER
THE 12TH, 1874, IN HIS 41ST YEAR, WAS CAUSED
BY BLOOD POISONING INCURRED IN THE DISCHARGE
OF HIS DUTY.

Correspondence.

"Audi alteram partem."

ARMY SANITARY COMMISSION.

To the Editor of THE LANCET.

SIR,—In THE LANCET of last week there are some severe reflections on the Army Sanitary Commission, the cause of which appears to have been that the Commission had failed to discover in certain cholera reports submitted to them from India support for one of the many theories of cholera propagation—viz., the cholera water-theory; and the somewhat extensive deduction is drawn from this default that there is nobody on the Commission competent to deal with questions of this class.

I am not aware what steps the Commission may take in this matter, and, as Dr. Fayrer, the sanitary adviser and representative of the India Office on the Commission, is with H.R.H. the Prince of Wales in India, I have in my private capacity thought it advisable to ask your indulgence to enable me to state simply the facts of the case, many of which appear not to be known.

First, then, as regards the deduction drawn from the premises. When the Commission was first formed the late Sir Ranald Martin was placed on it as sanitary adviser to the India Office, in which capacity he served till his death. He was succeeded by Dr. Fayrer, and I am quite sure that the simple mention of these two names will carry conviction to the minds of the medical profession that, whatever *laches* the Commission may have been guilty of in the matter of cholera theory, the interests of public health in India, so far as regards an intimate acquaintance with every point of importance in the most recent advances of pathology and etiology of Indian diseases, are as well, and have been as well, represented within the Commission as without it.

Second.—The Commission is composed of representatives from the War Office, India Office, Royal Engineers, Army Medical Department, and Local Government Act Office, and it took its present form in consequence of a recommendation of the Royal Commission on the Sanitary State of the Indian Army. It acts under instructions from the Secretary of State for War, and the Secretary of State for India; its functions are of a practical sanitary kind, and, as regards India, are directed to the improvement of barracks, hospitals, married quarters, the drainage, conservancy and water-supply of military stations, improvements in bazaars, native towns, and among the civil population generally. Many years ago suggestions on all these matters of principle were sent to India, and the Commission has ever since been in communication with the authorities on them. But although the Commission has no power to undertake pathological or etiological investigations, there is nothing in this department which escapes its notice, or the notice of the Sanitary Department in India. There is, indeed, no publication in which any new matter on these subjects is set forth in England, Germany, or France, which is not transmitted as soon as possible to India, and the Indian Government makes a money grant annually for this purpose. There is besides a scientific staff in India engaged on these very investigations. The duty of the Army Sanitary Commission is to use all information of this sort as a basis from which to deduce principles of practical utility, and even this cholera water-theory has been taken into account for a number of years past. The literature of water analysis in India, undertaken at the instance of the Commission, has no equal in Europe. The results of it led to the recommendation by the Commission of certain principles for the protection of water-sources at Indian stations, which, when fully carried out, will render the pollution of drinking-water by cholera material, or indeed by any other impurity, physically impossible. I could give other similar illustrations, but this, as connected with the present subject, will be sufficient to show the use to which etiological doctrines have been and will continue to be put. Of course there are other and most important applications of these doctrines which do not come within the functions of the Commission. These belong to the Army Medical Department under its own chiefs. It is not necessary that any pressure should be adopted in this direction, neither would it be submitted to. There is only one way in which persons holding such doctrines strongly can get them adopted by the Army Medical Service, and that is to support them by facts and reason.

Third.—The executive work of sanitary improvement is all done in India by Government; by its public works department, sanitary and vaccination services, commissioners, municipalities, local magistrates, and even by native village officials; and, as regards regiments and stations, by the great Indian Army Medical Service and Cantonment Committees. In the whole history of human progress there is nothing more remarkable than the advance of sanitary improvement in India during the last ten or twelve years. There is nothing in the West that can be compared with it. The work is very far from being done, but very much has been already accomplished.

Fourth.—With regard to criticisms which have been made on the form and contents of the Commission's "Remarks," it seems necessary to state that these are determined by the nature of the documents submitted to the Commission from every part of India, and by the terms of the reference. The Commission has considered it to be advisable to give a terse account of the principal parts of the documents (a recent one contained 500 printed folio pages), as well as to call attention to the main practical points, which are all considered with reference to the principles of sanitary improvement long since adopted in India. It need scarcely be said that the remarks embody the views of the sanitary and engineering advisers of the India Office serving on the Commission. No practical difficulties have arisen from the form of the "remarks," and they have aided in the advance of sanitary improvement.

But, after all, the main question is, What has been the practical result of all this work, even admitting that it is small in amount when compared with the vastness of the field? The reply is, that wherever sanitary work has been done, in cities, municipal towns, villages, and public institutions, there has been improvement in the public health, of which striking examples are afforded by improved gaols, many of which may now be used as illustrations of what may be done for the native population. But the British Army, from its complete system of statistics, affords the most striking illustration of the effect of these improvements. At the time when the Royal Commission on the Sanitary State of the Indian Army began its inquiry in 1859–60, the average death-rate among British troops in India was 69 per 1000 per annum. Last year (1874) it was a shade above 13½ per 1000 (13·58). This, however, is a fact, not an average, because there was little cholera about (only 11 deaths in the whole army). In old times the sick in hospital averaged about 10 per cent. The proportion is now less than half this amount, the difference representing the number of men in the ranks who formerly would have been in hospital. Perhaps no better justification of the present method of carrying out Indian sanitary work could be adduced. As already stated, this communication is simply intended to state facts, and not to discuss controverted questions.

I am, Sir, yours, &c.,

London, Nov. 24th, 1875. JOHN SUTHERLAND, M.D.

THE CASE OF SUPPOSED BLOOD-POISONING.

To the Editor of THE LANCET.

SIR,—With reference to the interesting case of supposed "blood-poisoning," the particulars of which are given by Dr. Dyce Duckworth in the last number of THE LANCET, will you permit me to suggest, with every respect for his opinion, that the evidence against the symptoms being due to malignant disease in the thorax is scarcely conclusive.

I understand from the report that Dr. Duckworth looks upon the enlargement of the thyroid body present in that case as part of a general infection of the lymphatic system; but in a case of primary cancer, occupying the mediastinum and root of the right lung, which I met with not long ago, and reported in a contemporary of April the 25th, 1874, enlargement of the thyroid gland was one of the earliest and most marked symptoms. It was uniform, firm, and smooth, and I regarded it merely as an evidence of obstructed circulation through the superior vena cava.

Primary intra-thoracic cancer, moreover, evinces a decided preference for the right lung, and it is remarkable that this was the side on which the respiratory changes described by Dr. Duckworth were heard. In my case there was the same paroxysmal pain and the same absence of pyrexia.

Dr. Duckworth states that at a time when the thyroid body was manifestly enlarged the patient "did not feel unwell." I think this was scarcely likely to be the case if septicæmia was the cause of the enlargement. In septicæmia also was pyrexia likely to be continually absent? As there was no evidence of leukæmia I cannot help thinking that the symptoms may have been due to malignant disease mplicating the bronchial glands and root of the right lung.

I have only ventured to make these comments as I have seen enlargement of the thyroid body in the case to which I refer, and also because it is evident that primary intra-thoracic cancer may go on, almost to the very close of the patient's life, without producing any symptoms save those which are due to obstructed circulation and respiration, and to the effects of nerve-pressure; emaciation, cachectic appearance, pyrexia, and night-sweats being possibly altogether absent.

I am, Sir, yours truly,
GEO. F. ELLIOTT, M.D.,
Nov. 22nd, 1875. Physician to the Hull Infirmary.

Medical News.

Royal College of Surgeons of England. — The following gentlemen, having passed the required examinations for the diploma, were duly admitted Members of the College at a meeting of the Court of Examiners on the 18th inst. :—

Blakiston, Arthur A., L.S.A., Wallington, Surrey.
Carcenac, Edward, Mauritius.
Carey, Adrian, Guernsey.
Cooper, Henry D., LS.A., Bengal.
Darker, Frederick W., Peckham.
Dobbie, Robert J. A., L.S.A., Budleigh Salterton.
Don, Arthur C., Hammersmith.
Gairdner, John, Maidenhead.
Godfrey, Benjamin G., Clapham, Surrey.
Harmer, James R., L.S.A., Birmingham.
Hopgood, Wm. C., L.R.C.P. Ed.. Chipping Norton.
Jackson, Philip J., L.S.A., Merton, Surrey.
Knight, John T., L.S.A., Sandiacre, Derby.
Lewis, Joseph J., Milborne Port, Somerset.
Lloyd, James H., Milner-street, Chelsea.
Mathias, James, L.S.A., Cardigan.
Price, Henry E., Stamford-hill.
Shann, Frederick, Brompton.
Sherrin, Francis M., Camden-road.
Smith, Stephen M., Surbiton, Surrey.
Steddall, Thomas W., Pontypridd, South Wales.
Tredinnick, Ernest, Camborne, Dorset.
Twining, Frank T., M.B., Southport, Lancashire.
Ward, Charles, Greenstreet, Kent.

Of the 78 candidates examined during last week, 46 were approved and obtained their diplomas; 14 passed the examination in Surgery, and when qualified in Medicine will be admitted Members; and 18 failed to satisfy the Court of Examiners, and were referred to their professional studies for six months. There were also 18 candidates admitted members who had passed in Surgery at previous meetings of the Court, and who had subsequently obtained medical qualifications recognised by the College.

The following gentlemen passed the first part of the Professional Examination for the Fellowship of the College on Tuesday and Wednesday last :—

E. B. Gardner, St. Thomas's Hospital; W. L. Barker, St. George's Hospital; J. W. Smith, Guy's Hospital; G. Jackson, University College; F. Buller, Toronto and St. Thomas's Hospital; A. W. Pritchard, Bristol; F. F. Chavasse, Edinburgh and Birmingham; J. L. Jaquet, Westminster Hospital; W. R. Harrhy and A. S. Underwood, King's College; P. H. E. Freund, St. Thomas's Hospital; W. J. Roeckel and C. W. M. Moullin, St. Bartholomew's Hospital; A. H. Young, Edinburgh; E. W. Cottle, St. George's Hospital; A. Hensman, University College.

For the Final Examination for the Fellowship, which commenced on the 25th inst., there were 13 candidates.

Apothecaries' Hall. — The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on Nov. 18th :—

Blakiston, Arthur Alexander, Wallington, Surrey.
Harmar, Jas. Raffles, Newhall-street, Birmingham.
Gathergood, B. W., Terrington St. John's, King's Lynn.
Maples, Reginald, Spalding, Lincolnshire.
Pilkington, Henry, Liverpool.
Williamson, Geo. Edward, North Shields.

The following gentlemen passed the Primary Professional Examination on the same day :—

John Chadwick, Manchester Infirmary; J. Henry Lee Macintire, Middlesex Hospital; Gordon Money Roberts, Guy's Hospital; George William Sidebotham, Manchester Hospital.

The "Scotsman" states that Professor Huxley, having received the necessary sanction of the Lord President of the Privy Council and of the Royal Society, has accepted the invitation of the Senatus of the University of Edinburgh to take charge again of the Natural History Department during next summer session, Professor Wyville Thomson's term of absence having been prolonged in order to enable him to complete the work he is charged with in the *Challenger* Surveying Expedition.

Bequests, &c., to Medical Charities. — The Annual Report of the Taunton and Somerset Hospital acknowledges legacies of £1000 under the will of Major-General Waddington, £500 under that of Mrs. Lark, and £100 under that of the Rev. C. J. Allan, and an investment of £1000 New Three per Cent. Annuities by Lady Anna Gore Langton. Mr. Abraham Mitchell has given £1000 between the three medical charities at Bradford, Yorkshire —viz., the Infirmary, the Eye and Ear Hospital, and the Fever Hospital. Mr. Wm. Robinson Johnson, of the Cliff, Wybunbury, Cheshire, bequeathed £500 to the Manchester Infirmary, £100 to the Chorlton-in-Medlock Dispensary, and £100 to the Ardwick and Ancoats Dispensary. Mr. Wood, of Longthwaite, bequeathed £250 each to the Cumberland and Westmoreland Convalescent Institution at Silloth, the Cumberland Infirmary at Carlisle, and the West Cumberland Infirmary at Whitehaven. Lord Berwick has given £100 towards the building fund of the Eye, Ear, and Throat Hospital, Shrewsbury. Miss Calvert Jones, of Bath, has given £100 to the Swansea Hospital. The Dental Hospital of London has received £100 under the will of Mrs. Carmichael. £100 has been sent anonymously towards the proposed Cottage Infirmary at Andover. The City Orthopædic Hospital, Hatton-garden, has received £100 under the will of Mr. George Bond, and a third donation of £21 from the Fishmongers' Company.

Proposed United System of Drainage. — The Improvement Commissioners for the district of Surbiton having applied to the Local Government Board to direct an inquiry with a view of forming the urban sanitary districts of Acton, Chiswick, Croydon, Ealing, East Moulsey, Epsom, Eton, Ham Common, Hampton Wick, Kingston-on-Thames, Richmond, Staines, Surbiton, Teddington, Twickenham, Wimbledon, and Windsor, together with all or some of the rural sanitary districts of Brentford, Chertsey, Croydon, Epsom, Eton, Kingston, Richmond, Staines, Uxbridge, and Windsor, into a united district for the purpose of carrying into effect a system of sewerage, the board have directed Lieutenant-Colonel Ponsonby Cox, Royal Engineers, to hold a preliminary inquiry at the Commissioners' Office, Surbiton, on the 3rd prox.

Dr. William Sedgwick Saunders has been placed on the Commission of Lieutenancy for the City of London.

Medical Appointments.

Austin, Dr. J. A., has been appointed, provisionally, Medical Officer and Public Vaccinator for the Parishes of Tongue and Farr, Sutherlandshire, vice M'Calman, resigned.

Beatty, J., F.R.C.S.I., has been appointed Surgeon to the Rathdown Hospital and Dispensary, Monkstown, Co. Dublin, vice Wm. Plant, M.D., J.P., deceased.

Boodle, R. M., M.R.C.S.E., has been appointed House-Surgeon to the Rochdale Infirmary, vice Burke, resigned.

Briggs, Mr. W. P., has been appointed Demonstrator of Anatomy in Anderson's University, Glasgow.

Buchanan, W., M.R.C.S.E., has been appointed Surgeon to the Chatham Division of the Kent County Constabulary.

Bullmore, W. K., M.D., M.R.C.S.E., has been appointed Medical Officer of Health for the Falmouth Borough Urban Sanitary District.

Cole, R. M., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer to the Gloucester Union Workhouse, vice Cookson, resigned.

Davies, Mr. D., has been appointed Medical Officer and Public Vaccinator for the No. 4, or Leigh District of the Martley Union, Worcestershire, vice Moore, who was appointed but declined, having been appointed about the same time to the No. 1 District of the Ongar Union.

Devany, P. C., L.R.C.P.Ed., L.R.C.S.I., has been appointed Medical Attendant to the Royal Irish Constabulary, Sligo, and Strand Hill; and Medical Officer of Health for the Sligo Urban Sanitary District, vice Tucker, deceased.

Diamond, Dr. J., has been appointed Medical Officer and Public Vaccinator for the Parish of Muthill, Perthshire, vice Core, resigned.

Donovan, Dr. J. I., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Ballincollig Dispensary District of the Cork Union, vice Rountree, deceased.

Ellis, H. D., M.R.C.S.E., has been appointed Certifying Factory Surgeon for the Bournemouth District.

Govett, P. W., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the No. 5 District of the Plympton St. Mary Union, and Medical Officer of Health for the No. 5 Sub-district of the Plympton St. Mary Rural Sanitary District, vice Adkins, resigned.

Helsdon, C. V., M.R.C.S.E., has been appointed Medical Officer for No. 4 District of the Andover Union, vice Pike, resigned.

Hill, P. E., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Crickhowell District of the Crickhowell Union, Brecknockshire, vice Parry, resigned.

Horsfall, J. S., L.R.C.P., M.R.C.S.E., has been appointed Public Vaccinator for the Sowerby-bridge District of the Halifax Union, vice Wm. Elliott, M.D., resigned.

Jagielski, A. V., M.D., M.R.C.P.L., has been appointed a Physician in Ordinary to the Margaret-street Infirmary for Consumption and Diseases of the Chest, vice Smith, resigned.

Laird, J., L.K.Q.C.P.I., L.M., L.R.C.S.I., has been appointed Medical Attendant to the Royal Irish Constabulary, Rosses Point, vice Tucker, deceased.

Mackintosh, A., M.D., L.F.P. & S. Glas., L.M., has been appointed Medical Officer of Health for the Clay-lane Urban Sanitary District.

Packer, W. H., L.S.A.L., has been appointed Junior Assistant Medical Officer to the Gloucestershire Lunatic Asylum, near Gloucester, vice Cassan, appointed House-Surgeon to the Royal South Hants Infirmary, Southampton.

Saer, D. P., L.R.C.P.Ed., L.R.C.S.Ed., has been reappointed Medical Officer of Health for the Pembroke Urban, and Milford Port, Sanitary Districts.

Sarjant, J., M.D., L.R.C.P.Ed., M.R.C.S.E., L.M., has been appointed Medical Officer and Public Vaccinator for the No. 4 District of the Hailsham Union, Sussex.

Seagrave, C., L.R.C.S.I., L.K.Q.C.P.I., L.M., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Clonmany Dispensary District of the Inishowen Union, Co. Donegal, vice Coyne, resigned.

Shewen, A., M.D., has been appointed Assistant-Physician to the Metropolitan Free Hospital.

Stokes, Mr. W., Professor of Surgery, Royal College of Surgeons, Ireland, has been appointed a Governor of the House of Industry Hospitals, Dublin, vice Hamilton, deceased.

Terry, W. F., M.R.C.S.E., has been reappointed Medical Officer of Health for the Tiverton Urban Sanitary District: £50 per annum.

Thomas, L., L.R.C.P.Ed., L.F.P. & S. Glas., L.M., has been appointed Medical Officer and Public Vaccinator for the Amlwch District of the Anglesey Union, vice Hughes, resigned.

Webb, Mr. V. G., has been appointed Demonstrator of Anatomy in Anderson's University, Glasgow.

Wilson, J., M.D., C.M., M.R.C.S.E., has been appointed a Physician to the Worcester General Infirmary, vice Inglis, resigned.

Wood, W. E. R., L.R.C.S.Ed., has been appointed a Resident Physician's Assistant at the Middlesex Hospital, vice Davis, whose appointment has expired.

Births, Marriages, and Deaths.

BIRTHS.

Baker.—On the 21st inst., at Walter House, New Romney, Folkestone, the wife of Charles Eaton Baker, M.R.C.S.E., of a daughter.

Boggs.—On the 21st inst., at Paris, the wife of Alex. Boggs, M.D., late of H.M.'s Indian Army, of a son.

Hemsted.—On the 17th inst., at Wellingborough, the wife of Edwin Hemsted, M.D., of a daughter.

Liddard.—On the 16th inst., at Ladbroke-grove-road, the wife of Thomas Liddard, L.R.C.P.L., of a son.

Pottinger.—On the 23rd inst., at Melville Hospital, Chatham, the wife of Robert Pottinger, Deputy Inspector-General of Hospitals and Fleets, of a daughter.

Smith.—On the 15th inst., at Worthing, the wife of Cleveland Smith, M.R.C.S.E., of a son.

MARRIAGES.

Gunn—Gunn.—On the 17th inst., at Edinburgh, John Jamieson Gunn, M.B., to Isabella, daughter of the late Robert Gunn, Esq.

Russell—Brewer.—On the 17th inst., at St. Luke's, Westbourne-park, George Ireland Russell, M.R.C.S.E., to Emma, widow of the late John Brewer, Esq.

DEATHS.

Brown.—On the 27th ult., on board the Steam-ship "Sumatra," on the voyage from Aden to Bombay, James Brown, M.B., C.M., Surgeon in the P. & O. S.N.Co.'s Service.

Brown.—On the 14th ult., at Fraserburg, Cape of Good Hope, John Henry, infant son of John Brown, M.D., L.R.C.S.Ed., aged 7 months.

Chapman.—On the 19th inst., at Leckhampton, Henry Thos. Chapman, F.R.C.S.E., aged 69.

Eaton.—On the 15th inst., at Hamilton House, Moffat, James Eaton, M.D., formerly of the Hon. E.I.Co.'s Service, aged 69.

Greenup.—On the 23rd inst., at Farnworth, near Warrington, Henry Greenup, M.D., aged 65.

Henderson.—On the 16th inst., at Scorton, Yorkshire, J. F. Henderson, M.D., aged 32.

Jones.—On the 17th inst., at Weston-super-Mare, E. S. Jones, L.R.C.P.Ed., aged 31.

Roberts.—On the 17th inst., at Holyhead, John Roberts, L.R.C.P.Ed.

Ward.—On the 16th inst., at Northbourne, Chobham, Samuel M. Ward, M.B., aged 40.

Webster.—On the 19th inst., at Dulwich, Geo. Webster, M.D., aged 78.

Wilson.—On the 15th inst., at Whitby, John Wilson, M.D., aged 82.

Woods.—On the 19th inst., at Rathfriland, Co. Down, William Woods, L.R.C.S.Ed., aged 64.

[N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*]

Notes, Short Comments, and Answers to Correspondents.

Vivisection.

Dr. Arthur Gamgee, of Owens College, in a lecture at the Manchester Athenæum a few days ago, justified the restricted employment of experiments on living animals on the ground of the important discoveries which by its means had been made for the benefit of humanity, and the possibility of such experiments being performed with the infliction of but little real suffering on the subjects of them. The lecturer pointed out, however, that many interesting experiments are made on the living tissues of animals that had just died, which experiments, though properly included in the term "vivisection," involve no suffering at all. After deprecating the indiscriminating outcry which had been raised against physiological experimentation, Dr. Gamgee expressed his belief that the forthcoming report of the Vivisection Commission would be of a nature to set aside the fears and apprehensions which had arisen in the public mind, and that the Commissioners would show that the horrifying statements which had been made could not be borne out by facts.

Aristotle's Notion of Right-Handedness.

Mr. Pearson, of Emmanuel College, lately read a paper before the Cambridge Philosophical Society on "Aristotle's Notion of Right-Handedness," and added some remarks on a theory of his own on the subject. After referring to the paper by Dr. Hollis on this subject, communicated last year (Nov. 30th, 1874: *Journal of Anatomy and Physiology*, vol. ix., p. 263), the speaker stated that he had been led by Aristotle's great reputation to inquire what his views on the subject might have been. Partly from a perusal of much that Aristotle has written on the subject, but mainly from the new Index by Prof. Bonitz, he gave a *résumé* of the passages bearing on the subject. These passages seemed to show that Aristotle considered (1) that the right hand or side was naturally the source or origin of motion, (2) that in nearly all living creatures capable of motion it is the better or stronger side, (3) but that while the heart is always the origin of vitality, it is in the human race only set towards the left side of the body; in all other living creatures it is in the centre of the body or trunk (ἐν μεσῷ κεῖται τοῦ ἀναγκαίου σώματος). And though it may be a fair question how far Aristotle was misled by the preferential use of the right hand by the human race to attribute an excellence in the right side to the animal world, there can be no mistake about the distinct language in which he does so. Some observations were added about the terms in which Mr. Lewes in his work on Aristotle (1864) criticises some errors into which that writer has fallen in his works on Natural History, while it was admitted that he is probably right in considering that there is no reference in Aristotle's writings to the anatomical examination of any but animal subjects; though the fact that Macrobius ascribes to Erasistratus and Herophilus, two celebrated physicians of the succeeding generations, the practice not only of dissection but of vivisection of human bodies, shows, if the story is true, that public opinion could not have been quite unprepared for it. Mr. Pearson also referred to a passage in the *Encyc. Britann.*, art. Comp. Anatomy (§§ 202—205), ed. 1810 (but not occurring in later editions), in which the preferential use of the right hand is discussed, and ascribed to a natural peculiarity in the form of the subclavian and carotid arteries on that side, and in which it is stated that a similar preference for the right side may be traced in some dogs, if not in horses. The speaker said, however, that he would not answer for the existence of such a preference himself in those animals, nor in the lion and camel, to which Aristotle (and Pliny after him) especially ascribe it. He concluded by exhibiting a lobster, of which the right claw is distinctly larger and stronger than the left, as is specially mentioned by Aristotle (οἱ καρκινοὶ…τὴν δεξίαν ἔχουσι χηλὴν μείζω καὶ ἰσχυροτέραν…).—Mr. Neville Goodman considered that the paper had only shown the superiority of the inductive to the speculative method of reasoning, although proving Aristotle's skill in adducing facts from the great repertory of nature in favour of his own view. He quite admitted that many facts indicate the right side as having a preferential motor function. In addition to the examples given, the whole order of Gasteropods were mentioned as having their chief organs on the same side, while the ordinary snail exhibits an excessive development in the same direction. To this rule, however, there are many exceptions. Again, the flat-fish (Pleurovectidæ), though quite asymmetrical in their form, have not by any means always their motor function to the right; the sole being generally developed to the right, the turbot to the left. He doubted the preferential use of the right side in animals; and though in ancient art the left leg is advanced, the position he thought purely conventional.

Mr. S. C. Ashley.—We regret we cannot comply with our correspondent's request.

Typhoid and Distemper.

To the Editor of The Lancet.

Sir,—The communications published in your journal from "H. H." and Mr. Smithard, relative to the supposed connexion between distemper in the dog and typhoid in man, open up a question of especial interest to us veterinary surgeons.

Whilst fully admitting the possibility of such a mode of origin of enteric as that suggested by "H. H.," my experience of distemper in the dog is that no fever of any kind has ever seemed to be communicated to any of the attendants on many cases, nor after post-mortems thereof. A family employing a coachman, and calling in a veterinary surgeon to attend upon a Newfoundland dog, would presumably occupy a *large* house. The family being from home, the coachman *slept* therein; the watercloset and cistern arrangements having been at comparative rest some time, if as imperfect as they are in many large houses, might have allowed an emission of sewer gases, or contaminated the water-supply, of which probably the coachman and his guest partook in some form or other; the coachman, imbibing (and perhaps inhaling) larger or repeated quantities of the water or gas, or both, succumbed. If the house was subjected to the precautions which the occurrence of a case of typhoid would render imperative before reoccupation, the non-appearance of further cases therein would not exclude my hypothesis that the enteric of the coachman and groom might be due to causes referable to the house.

As the subject is one of undoubted importance, it would be satisfactory to be assured that the probable causes adverted to with respect to the domicile had been carefully eliminated.

I am, Sir, yours faithfully,
Thomas Paton,
Veterinary Surgeon, Army Service Corps.
Dublin, Nov. 17th, 1875.

Mr. Henry M. Fernie.—The qualifications are very good, but are not in accordance with the copy of the rule as sent to us in our correspondent's letter. The rule of the infirmary should be adapted to the existing state of law and opinion.

Manchester Royal Infirmary.

Dr. J. E. Morgan, Physician to the Manchester Royal Infirmary, has addressed a third letter to the *Manchester Guardian* in reference to the removal of the institution with which he is connected—a subject on which we have already commented. In this communication Dr. Morgan enters into a consideration of the part of Manchester most suitable for a new hospital, and points out the merits of the site selected by the Medical Committee for the building—namely, a plot of ground of twenty-one acres at Rusholme, on the southern side of the town. The claims of this site are made to rest on its possession of the four features which, according to Miss Nightingale, ought to characterise the position of a hospital: "First, and before all others, purity of the atmosphere; second, the possibility of conveying the sick and maimed to it; third, accessibility for medical officers and for the friends of the sick; fourth, convenient position for a medical school, if there be one." The number of beds occupied in the present infirmary averages 200, but the proposed hospital would accommodate 400 in-patients, and there would be ground and space sufficient to admit of the construction of new wards, when required, capable of holding 200 additional beds. The cost of the purchase of the land, the erection of the buildings, the furnishing the wards, &c., is estimated at £220,000.

Adelphos.—We are not able to give the required information.

Military Midwifery.

To the Editor of The Lancet.

Sir,—There is no class of women who are worse off for medical attendance during labour than soldiers' wives; for, above the rank of paupers, they cannot command medical attendance from the union; they are, for the most part, too poor to pay a qualified practitioner; and the regimental officer either finds himself unfit or unwilling to undertake the office of accoucheur. The result is that in garrison towns old "Sarey Gamp" still flourishes with all the disagreeable and dangerous sequelæ of crass ignorance, and the medical officer is frequently sent for to attend some of the most serious accidents of childbirth, resulting from the unskilfulness of such women, who, without the rudiments of the art they profess, are permitted to call themselves midwives and practise in barracks, but only too willing to saddle any responsibilities on the medical officer of the corps. If women and children belonging to a regiment are entitled to "medicine and attendance" according to regulations, surely the authorities ought to provide *qualified* midwives, or hold their own medical officers responsible for the duties; and to illustrate the necessity for such a proceeding I subjoin notes of four cases which occurred in my own practice within a few months.

Case 1.—A "midwife" called upon me, and asked for "some ointment for the piles" for one of her patients whom she had delivered two days previously, and on giving what passed for a fair description of external hæmorrhoids, she got some gall-and-opium ointment to apply. Two days afterwards she came to say that Mrs. —— was in great pain, and the "piles" were very large. On visiting the patient, I found her in extreme agony, with about eight inches of the rectum protruding, the gut deeply congested from strangulation, and, I need scarcely say, I found a very serious difficulty in returning it, and a tedious convalescence ensued.

Case 2 was attended by a medical practitioner, who lived three miles from the patient's house. He had spent the greater part of a night with her; the labour was tedious, but without complication, and he left her apparently in the most favourable circumstances. At 8 a.m. I was suddenly called to see her, and on entering the room a few minutes afterwards I found her lying on her back, totally insensible, her arms thrown up over her head, and with one gasp she expired before I was ten seconds at her bedside. I do not know the cause of death, and, strange as it may seem, *no one ever asked me!*

Case 3.—At the request of a "midwife" I was sent for to see a woman who had been delivered of a child ten hours previously, and on my arrival I was informed that the head of a second child was "in the birth." On examination I found the placenta lying in the vagina, and it was removed without the slightest difficulty. This the midwife had mistaken for a second child's head, and so entailed upon me a three-mile walk on a cold and dirty night.

Case 4.—Also attended by a pseudo-midwife. When called I found the placenta had been retained for *fourteen hours* without any effort having been made to remove it. There was hour-glass contraction of the uterus, and it was only by the greatest perseverance and care that it could be extracted, much exhaustion and a long convalescence being the result.

There was also a fifth case, resulting in puerperal fever and death, in which I had reason to believe that retained placenta was the *origo mali.*

Yours faithfully,
November, 1875. Robert Nelson, Staff Surgeon, late R.M.A.

"Social Purity Alliance."

Mr. John Jackson, secretary of the above Society, sends us a disclaimer. The object of the Alliance is "to promote the practical recognition of the principle that the Law of Purity is of universal obligation on all men and all women alike, and thereby to counteract the causes of Prostitution." Mr. Jackson indignantly repudiates any connexion between Mr. Theodore Tilton of New York and the Alliance.

Alienist.—In the United States the certificate of one physician is held a sufficiently valid proof of the insanity of a person. The law requiring the certificates of two practitioners on oaeh was repealed in 1850—a retrograde step in the opinion of many. The form of certificate is as follows:—"I, A. B., physician, of the township of ——, in the county of ——, do certify that I have examined into, or am acquainted with, the state of health and mental condition of C. D., in the township of ——, in the county of ——, and that he is, in my opinion, insane, and a fit subject to be sent to the State Lunatic Asylum."

Epsom College.

We have received a letter from Mr. J. Taylor, F.R.C.S., enclosing one which he had received from Dr. Barnes at Epsom. We regret that any difference should have arisen between these gentlemen with regard to the treatment of Mr. Taylor's son. It appears that the boy was suffering from chicken-pox, and as Mr. Taylor felt anxious about him, he visited the College, and then considered that his son required medicines. Dr. Barnes resented this interference, and hence the correspondence in question. We agree with Dr. Barnes that the position of the medical officers would be intolerable if they are to be interfered with in their treatment of the cases committed to their care. At the same time the question is one requiring great delicacy and tact in dealing with. On the one hand, the medical officers should make every allowance for the natural anxieties of parents, while the latter should remember that the medical officers are appointed by the Council, who, being themselves members of the profession, are therefore excellent judges of the qualifications of the men whom they appoint to this office. We should say that, except in severe and urgent cases, the parents of the boys ought not to interfere.

Mr. Jas. W. Ayres (Greenwich) is thanked for his communication, but we think that our correspondent's suggestion would be considered an impracticable one.

Waterclosets in Churches.

To the Editor of The Lancet.

Sir,—I am on the Committee for rebuilding our parish church, and last year, when the conditions for the architects' competition were arranged, obtained the consent of the Committee that a watercloset in connexion with the church should be a *sine quâ non.*

We are now far advanced in the building, and in considering the locality best adapted for a safe to contain the documents and registries, came to the conclusion that the part set aside for the W.C. was peculiarly fitted for the safe, and it was agreed to appropriate it for this purpose. The architect pointed out how in a much more suitable spot a W.C. might be built. Great opposition has arisen to such an erection at all; the clergy oppose it, architects do not like it, and I may add that in the first instance a Church Building Society, from whom we sought a grant, actually almost refused it because there was a provision for a W.C.

I am told that scarcely any church has one, that it is unnecessary, open to all kinds of evils, and I am rather afraid that the idea will be shelved (though I do not intend to withdraw my proposition for one). I believe that it *was* always a necessary addition, and it *is* now much more so when churches are open all day, and some one must be on the spot many hours to take care of the contents of the edifice.

May I then ask, through you, from medical men in all parts whether it is a fact that in the churches near them, and especially in the modern ones, there are no W.C.s, and whether it is within their knowledge that evil has arisen from the absence of what I believe to be a necessary sanitary arrangement?

An early reply will much oblige, yours obediently,
William Tiffin Iliff, M.D.
Kennington-park-road, Nov. 23rd, 1875.

Relieving Officers and Medical Orders.

The absurdity of the system which gives power to the relieving officer to refuse relief ordered by the medical officer has received another illustration. A poor labourer suffering from starvation and slight pneumonia was ordered by the doctor, on Tuesday, 3 lb. of mutton. The relieving officer declined to give it, and told the poor man's wife that she should have come before the Board met. The next day the order for mutton was repeated, and the sagacious relieving officer refused again, but sent six loaves instead. Meantime the husband was craving for meat, and could not eat bread. His weekly wage prior to his illness was ten shillings. He had five children, three of whom were unable to work. It is therefore easily intelligible that his reserve of vital forcc was slight. He died on the Friday. The post-mortem revealed nothing but an empty stomach and slightly inflamed lung. The jury requested the coroner to administer a severe rebuke to the relieving officer. They would have done still better to have requested him to draw up a rebuke of a system which allows a relieving officer to withhold relief in such a case, though ordered by a medical officer.

A. B. C.—We believe, first-class fare each way, and one guinea per diem for each day actually and necessarily absent from home.

Dr. H. D'O. Foote.—Yes.

"Affairs in Glasgow."

Our Glasgow correspondent writes as follows —

Dr. Russell has corrected the statement I made to you, "that a somewhat personal and hasty correspondence took place between the superintendent of the infirmary and Dr. Russell." "The fact is," he continues, "I have never written a line to the 'daily papers' on the subject, or directly or indirectly taken any part in the controversy, excepting officially through the minutes of the Local Authority."

As this statement in the first place questions the accuracy of my report, and in the second may mislead anyone not familiar with the dispute, permit me to say that the minutes of the Local Authority are public property. They are duly and fully reported in the daily papers, with the discussions which afterwards ensue. Any remark in the minutes is simply a letter addressed to the editor of the paper, and through the paper to the public.

Dr. Russell has elected to misunderstand the term "correspondence" which I used, and I regret that he has done so. Technically he may be right; practically, I hold, and from the accompanying document and paper which I furnish you, you must observe, that his excuse is a mere play upon words, for the facts of the "somewhat personal and hasty correspondence" have become notoriously public property.

INDUSTRIAL INFANTICIDE.

ONE of those half-told stories—under the guise of medical evidence,—chiefly remarkable for the waste of valuable information, is reported from Wigan. It is stated that an "infant met its death from failure of the heart's action caused by intestinal irritation," consequent upon being suckled by a mother who had been away all day working in a factory. The hypothesis set up seems to have been that the milk had been rendered "sour" by retention for many hours. We offer no opinion as to the plausibility of this presumption. There is probably just enough ground in fact to support a theory of causation something like that propounded. But is the explanation offered the true one? It would be a grave inference, if proved, that mothers labouring should not nurse their offspring, or, nursing, should not be allowed to labour. This was the deduction drawn from the facts. We venture to think that, before any conclusion is arrived at, it would be well to ascertain the precise medical data upon which the judgment is to be based. Unfortunately the Coroner's Court is not available for scientific purposes, and *evidence* is not trustworthy testimony to medical facts, whatever may be its relation to legal truth.

Multum non Multa.—The work referred to is adequate for the purpose, and is recent.

Mr. D. M. Ross.—Supposing the facts to be simply as stated, we do not see how our correspondent could have done otherwise than he did.

T. H. J., (Shirehampton.)—The questions for past examinations have been published in the Army Medical Blue-books.

INCORRECT WRITING.

To the Editor of THE LANCET.

SIR,—On page 299 in "Dougall's Art of Shooting" is the following:—"The difficulty of trapping the hooded crow and of holding the raven when trapped have induced the use of that detestable strychnine, the mere effluvium of which in an apothecary's shop, when making a purchase for a nobleman, so sickened me as to give me a lively horror of it ever since. *Horresco referens.*" Mr. Dougall should be told that strychnine is colourless and *inodorous.* I am, Sir, yours truly,

November 22nd, 1875. T. F.

Z. X. Y.—Yes, the beneficial action of jaborandi on diabetes has been observed, amongst others by Dr. Laycock, who published a paper on the subject in our columns in August last.

A Clinical Lecture

ON

DIAGNOSIS,

Delivered at University College Hospital on November 18th, 1875.

BY SIR HENRY THOMPSON,

SURGEON EXTRAORDINARY TO H.M. THE KING OF THE BELGIANS; EMERITUS PROFESSOR OF CLINICAL SURGERY IN UNIVERSITY COLLEGE HOSPITAL.

(*Reported by* Mr. G. BUCKSTON BROWNE.)

GENTLEMEN,—You will recollect I announced at our last meeting that the subject for our inquiry to-day would be the Diagnosis of Diseases of the Urinary Organs. Now let me remind you at first starting that the diagnosis of disease is the one important thing that you come to the hospital to learn.

I know that the youth, when entering on his professional career, and also that heterogeneous body which is designated "the public," and to whom he at present belongs, regard, and quite naturally, the treatment of disease as the great subject which is to occupy all his time and powers. True it is his final object, but it is essential for him to know that the art of diagnosis is far more difficult and important to attain, that it demands labour, study, and experience, and that without it treatment is useless, or even worse, for it may be injurious. But let him be assured that if the diagnosis be intelligently made, then treatment is comparatively easy.

It must be admitted, however, that there is some difference between medicine and surgery in relation to this statement. The medical art may almost be said to culminate in diagnosis. I can remember the time when to distinguish between mitral disease and functional disturbance was more a matter of guess-work than of demonstration. At that period the early presence of phthisis was undistinguishable, and the arrival of its later stages a subject for widely differing opinions even among experienced men. These conditions verified, however, as is quite possible to the advanced among you, thanks to modern methods of physical examination, there can be small difficulty about the treatment, and little difference of opinion.

In surgery the diagnosis is no less important, but the treatment is less easy. The operative measures which often follow demand practical skill and certain other qualifications. Even here, however, diagnosis must take the first place, because operative treatment, being often of a very grave character, cannot be undertaken until after a correct and intelligent appreciation of the facts has been obtained.

What is diagnosis? It consists, first of all, in the acquisition of facts; and, secondly, in obtaining legitimate inferences from those facts.

Now the acquisition of facts is one of the most difficult things in the world. No two persons ever agree in their statements descriptive of an occurrence to which they both have been witnesses. If I bring a case of disease before you here, and ask ten of you to take as many histories of it, I will undertake to say that each one will materially differ, and that I shall get ten histories, varying from each other in some important particulars. Each will be approximately true; none will be absolutely correct. You must then diligently learn to observe, and to do so well requires special qualities and much practice. Is it not a very striking illustration of what I have said, that if two witnesses relate precisely similar stories of any given event, the suspicion of collusion is always instantly suggested, and is, indeed, very naturally aroused? It has often struck me that the qualities which men of our profession require, and which we should endeavour to cultivate, are precisely such as are necessary to those who are engaged in the exercise of the legal profession; and the men who are really successful in either profession have much in common in intellectual character and attainment. In our profession, equally with that of the law, careful examination of the statement, acute and subtle cross-examination of the witness, and a keen pursuit of the simple fact are essential; and, finally, a calm judicial habit of weighing the facts when obtained. And in both professions the issues raised are equally weighty, and demand in either case the highest qualifications in the individual.

But next, I have not only to call your attention to the necessity for making a careful and accurate diagnosis, it is equally important that you should learn to make a *rapid* one. For it must be admitted that our proceedings differ from those of the law in this respect; for while, as we have seen not so long ago, several months may be devoted to the critical investigation of a legal claim, and a considerable period of time must mostly be expended on the proof or disproof of any allegation, our decisions are required without delay. While the doctors are deliberating the patient is dying. Hence you see that the ability to arrive at a diagnosis rapidly often constitutes the essence of success. This art, also, it is my aim to teach you so far as I can.

To this end, and what I have to say applies to all departments of our art, I advise you always to pursue a uniform method. Order and uniformity are essential elements in directing the necessary investigation; and after much thought and experiment, for my own private guidance as well as for yours, I have adopted the following system. Relative to the class of diseases we are studying, there are three methods of obtaining the facts required:—Firstly, by questions of the patient; secondly, by physical examination of the body; thirdly, by examination, chemical and otherwise, of the secretions.

First, by questions. There are four chief questions which I always employ, and always in the same order. They ought, with the minor inquiries which branch out of them, to determine six out of seven cases which come to you. They relate to four signs and symptoms more or less met with in patients affected with complaint in any part of the urinary organs. Frequent micturition; painful micturition; deviation in the character of the urine itself from the healthy standard; the addition of blood to the urine.

The first question, then, which I invariably ask to any patient so affected is, "Have you any, and, if any, what frequency in passing water?" Then, as a branch of that question, springing out of it, I ask whether the frequency is more by day or by night, or influenced by movements, or by any particular circumstance? How the question applies I will tell you afterwards.

Then, secondly, I ask whether there is pain in passing urine, and whether before, during, or after micturition? Inquire also if pain is felt at other times, and if produced or aggravated by quick movements of the body. The locality of the pain is also to be precisely ascertained.

Then I ask, as a third question, "Is the character of the urine altered in appearance, or is there anything unusual in the stream itself? Is the urine turbid or clear?" Possibly the patient will tell you that it is turbid, but you find, on questioning further, that it was passed perfectly clear, and only became thick after cooling or standing. Also, as arising out of this, you may often ask, "Does it vary much in quantity?" noting of course the specific gravity. The healthy standard, both as regards quantity and density, however, must be allowed very extensible limits, and both, I need not tell you, are very important elements in regard of renal disease. Then, as regards the stream itself, it may be small, forked, or twisted, or it may stop suddenly when flowing.

The fourth and last question is, whether blood has been passed in any way with the urine; whether the mixture is florid or brown, light or dark; whether the blood and urine are intimately mixed, or whether the blood is chiefly passed at the end or at the beginning of making water; or, lastly, whether it issues independently of micturition altogether.

After dilating on these inquiries and showing the manner in which, by their aid, the differential diagnosis of various diseases could be easily established, Sir Henry Thompson proceeded to describe the methods and instruments necessary for prosecuting physical and other examinations of the patient and of his secretions.

ON A CASE OF

SIMULTANEOUS EMBOLISM OF CENTRAL RETINAL AND MIDDLE CEREBRAL ARTERIES.

By W. R. GOWERS, M.D.,
ASSISTANT-PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, AND TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

Several cases of retinal embolism have been recorded in which there also occurred at some other time embolism of a cerebral artery. In the following case the two accidents appear to have been simultaneous. This rare coincidence, and the circumstance that a post-mortem examination enabled the diagnosis to be verified, render the case one of considerable interest. The patient was in University College Hospital, under the care of Sir William Jenner, to whom I am indebted for permission to publish my notes of the ocular condition, and the account of the general symptoms and of the post-mortem appearances, which are taken from the hospital case-book. It will be convenient to describe, first, the case in its general aspect; and, afterwards, the ophthalmoscopic appearances, and the results of the microscopical examination of the eyeball.

C. H. H——, aged thirty, carpenter, a healthy-looking man, was admitted Jan. 29th, 1870. In early life he had an attack of "low fever," attended by pains in the joints, followed by chorea and by weakness in his right arm. A year later he had a similar, less severe, febrile attack. During the six months before his present illness he suffered from cough, shortness of breath, and occasional slight hæmoptysis.

Without premonitory symptoms, he suddenly, when out walking, lost consciousness, was picked up insensible, and brought to the hospital. Soon after his admission he had partly recovered consciousness. There was then complete paralysis of the right arm and leg, and slight paralysis of the face. At the heart there was a loud systolic apex-murmur, with accentuated pulmonary second sound, and evidence of dilatation of the left ventricle, the impulse extending outside the nipple line in the fifth interspace. The urine contained no albumen.

On the following day he had so far recovered consciousness as to be able to speak, but answered "Yes" to all questions, uttering no other word. He turned on his back when told, but opened his mouth when told to shut his eyes. His stools and urine were passed unconsciously.

Three days after his admission he still answered "yes" and "no" indiscriminately to all questions. The hemiplegia continued unchanged. A day later, when asked where he suffered pain, he answered "in the head," but when asked his name he answered only "yes, no."

In this state he continued for some weeks.

On Februrary 21st it was noted that there was slight improvement both in limbs and speech. When the assistant, Mr. Price, went up to his bedside he attempted to say something, but only got out "ning." On Mr. Price suggesting "good morning," he immediately repeated it. When trying to converse with other patients, one of them began to sing a song, and while singing the first verse H—— hummed it with him, and then took it up and sang the second verse by himself, articulating the words fairly well. Afterwards, however, he was able to speak no better than before.

In the beginning of March he became worse, began to vomit food and cough up blood. The heart's action became more feeble and irregular, so that the murmur could be heard only with a few beats of the heart. The legs became œdematous, that of the right being greatest, the right arm also. The urine contained blood. The paralysis of the face had increased a little, but he had become able to move the leg slightly as he lay in bed.

By the middle of March all the evidences of cardiac failure were more intense, and on the 20th he got some œdema of the left arm, with hæmorrhagic spots up to the bend of the elbow. Signs of effusion into the right pleura showed themselves. On the 25th the distension of the left arm became extreme, bullæ formed on the right foot, and hæmorrhage occurred from the nostril. He lingered until the 29th, when he died.

Post-mortem examination.—Brain: There was a little excess of fluid under the arachnoid, but no general flattening of convolutions. The ventricles contained no excess of fluid. The right hemisphere was healthy throughout. In the left hemisphere were two lesions. The smaller was an area of softening on the outer surface of the left hemisphere, at the posterior part of the parietal lobe; it measured one inch by three-quarters. The two corpora striata presented a marked difference. The left was less full than the right, especially behind; the lining membrane of the ventricle over it was opaque, and the vessels too numerous; and at its junction with the optic thalamus it was softened over an area three-quarters of an inch in diameter, and of a yellowish colour. On section the disease did not extend into the optic thalamus, but passed outwards to the fissure of Sylvius, the tint of the softened portion varying from creamy white to pale orange. Convolutions of the island of Reil destroyed; lowest frontal convolution a little damaged. The arteries at the base appeared healthy. The right middle cerebral contained fluid blood. In the left middle cerebral, within the Sylvian fissure, was a clot half an inch long, colourless, firm, easily detached near the orifice of the artery, but above adherent to the inner coats. On each side of the clot was a little fluid blood. Branches from this occluded artery passed directly into the diseased portion of the corpus striatum. The anterior cerebrals and anterior communicating arteries were empty. The heart was much diseased. The mitral orifice was thickened and roughened, and calcareous on its auricular surface. Old clots were contained in the auricular appendices and in the apex of the right ventricle. In the lungs were numerous angular patches of pulmonary apoplexy. Each kidney contained an infarct pyramidal in shape, the base on the surface. A similar infarct was contained in the spleen.

Condition of eye.—Four days after his admission into the hospital, and five days after the onset of the paralysis, an ophthalmoscopic examination was made for the first time. Only the indirect method of examination was employed. The fundus of the right eye was found to be normal. In the left eye the optic disc could not be distinguished, being veiled by a greyish-white cloud; its position could be noted by the convergence of the vessels. Another white cloudy opacity of considerable size existed in the retina near the yellow spot. Both these had soft edges, were moderately white, and the retinal vessels appeared partly concealed by them. The arteries were small, the veins large and distinct.

On the following day the appearances in the eye were nearly the same, the white opacity in the centre of the fundus being continuous with that near the optic disc. In front of the former a distended vessel crossed transversely just above the position of the yellow spot, and small twigs passing from this vessel at right angles on each side were abnormally conspicuous against the white background. On examination it was clear that he could not see with this eye.

During the next week these white patches gradually lessened, and the outline and surface of the disc became clear. As the vessels became more visible the diminished size of the arteries was distinct. By Feb. 18th the large white patch near the yellow spot had gone, leaving only a little irregular cloudy and granular whiteness. The optic disc was quite distinct in its inner portion, while the outer half was still somewhat hazy. A line of whitish opacity extended upwards and outwards towards the yellow spot, and, curving round and becoming fainter, blended with the traces of the mischief near the yellow spot. In the first part of its course it accompanied a vessel. Below the disc was another limited opacity bounded on each side by a vessel.

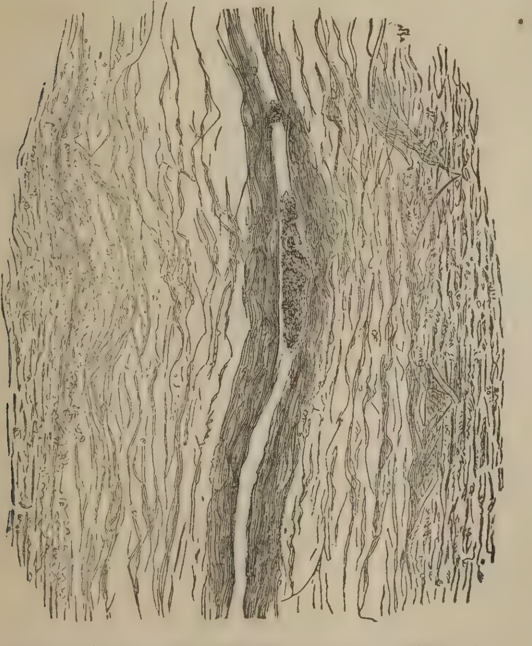
The veins were all perceptible and tolerably uniform. The arteries were much narrowed on the optic disc and for some distance around; they appeared mere threads. Not very far from the disc, at a distance variable in different vessels, but usually about twice the diameter of the disc, they again became conspicuous. There was a distinct darkish opacity of the retina all round the optic disc.

On March 1st the optic disc remained clear; the vessels, both arteries and veins, had diminished in size, the former, on the disc, being reduced to the merest threads. They were narrower at a distance from the disc than formerly. In one vein the column of blood was interrupted, for the vessel appeared as if empty for a little space.

On March 13th it was noted that the disc had become whiter, and its edges well-defined and clear, but a little uneven. The remains of opacity below and above the disc were still there, but less conspicuous. The veins were rather smaller than when last examined, and the diminution in size was chiefly noticeable near the disc, where they appeared considerably narrower than in the equatorial region. One small vein could not, with the indirect image, be seen close to the disc, but reappeared a short distance away. The arteries on the disc itself were just visible as lines, and some of them could not be distinguished against the choroid near the disc. All, however, became more perceptible at about two disc-breadths from its edge, and towards the equatorial region became much larger than near the disc, though smaller than when first observed. This condition continued until he died.

For microscopical examination, longitudinal sections of the optic nerve and disc were made, after hardening in weak chromic acid. The central artery in the optic nerve was dilated here and there, but for the most part so contracted that its calibre was reduced in places to a mere line. It was somewhat tortuous. The walls were thick, but only in proportion to the contraction of the artery. There was no plication of the inner layer. The dilated portions corresponded in some instances to the passage of a branch from the artery into the substance of the optic nerve. Just behind the division of the artery in the disc was a dilatation of some size. But in the disc itself, the main branches of the artery were reduced to very narrow dimensions, the cavity of one being only $\frac{1}{2000}$ in. in diameter, and that of another reduced to a mere line.

Here and there, chiefly in the substance of the nerve, but to a less extent also in the disc, minute granular masses could be seen in the vessels. The largest of these, represented in the woodcut, was situated in the main trunk in the substance of the optic nerve, about one-eighth of an inch behind the lamina cribrosa. It is an elongated plug, $\frac{1}{300}$ of an inch in length, and about $\frac{1}{800}$ of an inch in width, coarsely granular in appearance, containing many dark points. It apparently did not quite fill the vessel, having doubtless shrunk from the sides while the specimen was being hardened. A little distance in front of this was a small spherical mass. Further back the vessel was for some distance reduced to a very narrow size, hardly any cavity being visible; but here and there a little granular mass could be noticed within it. Further back it again widened out, and then narrowed. In one of the narrowed arteries on the disc a quantity of granular material could be perceived. The veins on the disc were reduced in bulk, but were much larger than the arteries. No capillaries in the disc or about the lamina cribrosa could be perceived. In the retina beyond the limits of the disc, however, about a disc's breadth from its edge, numerous dilated capillaries could be seen, running inwards through the nerve-fibre layer, some vertically, others at an inclination. They appeared as if passing from the choroid to the surface of the retina; but they could not be traced towards the choroid beyond the cellular layers of the retina.



Longitudinal section of central artery of retina, one-eighth of an inch behind the lamina cribrosa. On each side is loose cellular tissue, and beyond this the longitudinal nerve-fibres are indicated. Within the contracted vessel is an oval granular mass, and in front of this a smaller spherical body. Magnified 300 diameters.

The nuclei in the optic nerve were not more abundant than normal, but the nerve-fibres showed some commencing degeneration, a few globules of myelin being scattered among them. The disc was not swollen, its height above the level of the choroid being within the normal limits. The minute round nuclei which commonly lie among the nerve-fibres in the disc were increased in number, and in places were accumulated in oval heaps between the bundles of nerve-fibres. The layer of nerve-fibres passing on to the retina appeared a little swollen; but its thickness, a disc's breadth from the edge of the disc, was only $\frac{1}{300}$ of an inch, the fibres being here and there very slightly varicose, and lying less closely together than is usual. The cellular layers of the retina near the disc were in some parts normal, or nearly so, the ganglion cell-layer, the two nuclear and the internuclear layers being distinct, the former only in places a little thickened by the increase in the number of corpuscles composing them. (The layer of rods and cones was nowhere distinguishable as such, doubtless from the time which elapsed after death before the post-mortem examination was made.) On another side of the disc, however, probably where the opacity was noticed during life, the whole thickness of the retina was infiltrated with minute corpuscles resembling those of the nuclear layers. In these layers they were more closely aggregated, but they filled also the internuclear layer, and were scattered less closely through the molecular layer. The retinal layers were also a little sinuous. These changes were noted especially in the portion of the retina beneath the thickened nerve-fibre layer.

Near the macula lutea some irregularities in the surface of the retina could be noticed on looking at it with a simple lens. These depended partly on ramifying vessels and partly on the retina being raised in minute folds. The microscopical examination showed considerable though variable change. In some places all distinction of layers was lost; small round corpuscles resembling those of the nuclear layers, but staining less readily with logwood, infiltrated the whole thickness of the retina, the only other structure perceptible being the remains of the vertical fibres of the retina, themselves thickened, among which the nuclei lay. In other places the fibres of the internuclear layer (here, of course, always wide) were separated, spaces between them being left, and the nuclear layers being normal, as in simple œdema. In some places round corpuscles were scattered through this layer; in other parts the molecular layer was infiltrated with small round corpuscles lying amid a granular matrix. The external nuclear layer was also in places considerably thickened. Where the retina was raised in a fold, this layer on the concave side was sinuous, and between the contiguous folds the layer of rods and cones had disappeared, and the space was filled up by a considerable quantity of granular material, in which a few round corpuscles could be distinguished. The pigment epithelium was in this part in close contact with and adherent to the external nuclear layer.

Remarks.—There can be no question as to the nature of the case. The discovery of masses of granular material in the central artery and its branches, and the absence of any hæmorrhage around the vessel, the occurrence of undoubted embolism in the middle cerebral artery and in the kidneys and spleen, the correspondence of the retinal changes, vascular and parenchymal, to those observed in other instances of embolism, render the nature of the case unquestionable. The condition of the retina when first examined agrees closely with that observed in other cases a few days after the occurrence of embolism. Hence it is probable in the highest degree that the retinal and cerebral embolisms were simultaneous.

What was the position of the obstruction? I do not think that the plug figured can be regarded as that which effected the closure of the artery. Its size is not sufficient, and there is no narrowing of the vessel at the spot to account for the arrest of so minute a plug. The artery also was contracted behind it, and the contraction extended, with intervals of dilatation, as far back as the examination of the optic nerve extended, which was nearly, but not quite, as far as the entrance of the central artery into the substance of the nerve. The artery was traced, with the scalpel, from its origin from the ophthalmic as far as its entrance into the nerve, and no plug was seen, but a microscopical examination of the vessel was not made. The numerous fragments of fibrin to be seen in the vessels of the nerve and disc show how much material must have been discharged into the vessel at the time of the embolism. It is probable that the chief obstruction was situated where the artery enters the nerve.

A ready collateral circulation must have been established, for the arteries, as seen with the ophthalmoscope, maintained their thread-like dimensions only for a very short distance after leaving the disc, and then resumed a distinct though diminished contour. The blood reached them no doubt from the posterior ciliary arteries. It is often assumed that the vessels of the disc form an important part of the means of communication. The opinion rests on the statement of Leber that the disc is supplied by the posterior ciliaries. But surely the marked and increasing pallor of the disc in this and in almost all cases of embolism is in contradiction to the assumption. An exception was the case of Wecker's,* in which an obstruction of a branch of the artery was followed by increased vascularity of the corresponding portion of the disc. But the case stands alone. Pallor of the corresponding part of the disc is more common, as Mr. Nettleship has lately pointed out; and in a patient of Mr. Streatfeild's, whom I saw some time ago, in which there was obstruction (doubtless from embolism) of one branch, with corresponding segmentary loss of sight, there was not a trace of increased vascularity in the corresponding portion of the disc. The pallor of disc in these cases depends, as Gradenigo† has pointed out, on anæmia, rather than on tissue proliferation. No capillaries were visible, although carefully looked for, in the case I have just described; and neither the tissue-formation nor the degeneration of the nerve-fibres was sufficient to account for the pallor. But there was distinct distension of small vessels in the retina outside the limits of the disc, and it is, I think, clear that it was by the vessels near the papilla, and not by those in the disc, that the collateral circulation had been set up.

The retinal appearances, as seen with the ophthalmoscope, do not differ in any material point from those of most other cases recorded. It is, however, to be noted that when first examined, five days after the presumed onset, the opacity of the retina was as marked around the disc as around the macula lutea. Moreover, the red spot at the macula lutea, so often described, was absent.

This fact is of interest in connexion with the diagnosis of embolism within the artery from hæmorrhage around it. The absence of a red spot at the macula and the presence of early infiltration around the disc are given by Magnus as diagnostic indications of hæmorrhage around the nerve. In the case now described, unquestionably embolic, the spot at the macula was absent, and by the fifth day the infiltration around the papilla was very marked.

The anatomical changes in the retina corresponded to the opacity observed during life, and still present, although in less degree, at the time of death. They indicate more structural change than is, I think, commonly supposed to occur in these cases. The adhesion of the pigmentary epithelium to the outer nuclear layer may perhaps be taken as evidence that the destruction of the layer of rods and cones at this part was not a mere post-mortem change, but occurred during the active processes consequent on the arterial obstruction.

ON A CASE IN WHICH IRRITABILITY OF THE FEMALE BLADDER OF FIFTEEN YEARS' STANDING WAS CURED BY DILATATION OF THE URETHRA AND NECK OF THE BLADDER.*

BY H. BENDELACK HEWETSON, M.R.C.S.

THE notes of the case I am about to relate are of extreme importance in connexion with an operation, still on its trial, introduced by Mr. Pridgin Teale, and but recently published,† which comprises dilatation of the urethra in the female for the relief of irritability of the bladder, and, as in this case, occasional retention of urine. The absolute success attendant upon its performance in some cases, and its partial, if not complete, failure in others, render it incumbent on us to keep strict records of the symptoms, general as well as local, which affect females the subjects of irritable bladder upon whom this operation is performed. The extent to which the dilatation of the urethra is carried should especially be noted, since the partial or complete failures may possibly be the result of too cautious stretching from fear of producing incontinence of urine. Moreover, the general symptoms must be taken into account, for it may be that it is upon them the surgeon is consulted, without the slightest reference being made (as this case will show) to the more delicate point of irritability of the bladder; when it is upon the latter trouble that the general malaise depends.

Following are the notes of the case:—

Miss M——, aged thirty-six, sent for me on the night of March 3rd, 1875. On arrival at her home, I found her to be suffering intensely from retention of urine. I relieved her (by the use of the catheter) of a large quantity of urine, such an amount as must have distended the bladder nearly if not quite up to the umbilicus. This point I did not test, being anxious to relieve her without delay from the worst agony of retention. The retention returned in a day or two, and I had again recourse to the use of the catheter.

Her previous history is as follows:—That she was a perfectly strong and robust woman, following the *arduous* duties of a "present day" schoolmistress until fifteen years ago, when she was seized with an inflammation of the bladder, for such it was termed by her medical attendant. This was followed by the formation of a small abscess in the region of the urethra, which discharged of itself. Since that time her health has been bad, preventing the continuance of her calling. She states that since her recovery from this attack, her nights have been wakeful and disturbed by being constantly "every half hour or hour" obliged to get up to pass small quantities of urine with great effort and some pain. She is low and depressed, with almost constant headache, loss of appetite, and continual bearing down, resulting in a total unfitness for prolonged exertion of any kind. She has lost flesh considerably, and has for several years been set down by her numerous friends and medical advisers, to whom she had made no reference to her urinary troubles, as a confirmed invalid. These symptoms were complicated a year ago by pain in passing the motions, which were infrequent and confined. She had not been seized by retention of urine previous to March last. In February last she was, with "questionable propriety," advised to come to Leeds to stay with some friends for the good of her health.

On examination I found the orifice of the urethra to be completely surrounded by warty growths of a considerable size, and on examining the rectum the introduction of the finger was impeded by a very tight sphincter ani. The rectum was baggy, and there was a small external pile. The uterus was in its natural position, and the catamenia were, and had always been, regular, and the urine was natural. Not being able to estimate to what extent the retention was due to the warty growths, and seeing she was suffering considerably from rectal difficulties, I deemed it advisable to negative the possibility of the retention being caused by the warty growths by removing them, and whilst the patient was under the influence of an anæsthetic stretching the sphincter ani with the forefingers introduced back to back sufficiently forcibly to paralyse it for a time and allow the sore produced by the snipping off of the pile to heal; in the same way as one would cure a fissure of the anus, by setting the spasm of the sphincter ani at rest, which, constantly contracting, might possibly be an element, through reflex action, in helping to keep up the vesical irritability.

---

* Read before the Leeds and West Riding Medico-Chirurgical Society, Oct. 1st, 1875.

† Vide THE LANCET of Nov. 27th, 1875.

Accordingly, on March 5th, chloroform having been administered, I completely carried out the above suggestions. The result of this was, that during the next few weeks relief was given to the retention of urine and to the pain in passing the motions; but there was no relief at all from the vesical irritability. Her general condition, with these exceptions, continued as before, and there was a return of the retention of urine at the end of three weeks from the operation.

I had clearly told her a second operation would possibly be necessary should the first fail to give relief, and accordingly, on April 11th, I again placed her under the influence of chloroform, and introducing Weiss's female dilator into the urethra to the extent of about two inches, I then *slowly* separated the blades of the dilator, stretching the urethra so as to admit of the introduction of my forefingers within the bladder while the parts were on the stretch. On closing the blades and withdrawing the instrument, the urethra contracted upon my little finger, so as sensibly to grip it when introduced into the bladder, the coats of which were thickened. There was no foreign body or stone to be detected.

She was very much upset by the chloroform-sickness, which continued more or less all night; there was, however, *no more irritability of the bladder, no retention, no incontinence produced,* and, to use her own words, "I have not passed water so freely for years"; nor had she retained it so long without being disturbed, for the first time she made water was in the evening after the operation, and she was not disturbed during the whole night.

April 14th.—She slept the night through, and awoke with little or no headache, retaining and passing her water quite naturally with the exception of some soreness.

16th.—She complains of slight pain while passing water, but perfect facility.

19th.—She got up in the evening complaining of none of her former symptoms, having lost completely all trace of vesical irritability in eight days from the dilatation of the urethra.

Her progress now continued to be satisfactory and very rapid.

May 4th.—She reports her old symptoms to have all disappeared. She sleeps and eats well, and takes a fair amount of exercise.

At this stage I ordered her into the country, where she resides, and returning on May 31st, she reported herself as perfectly well, and has gained three stones in weight. On the day previously she had walked a distance of eight miles without feeling more than ordinary fatigue, and remarked that before the operation "she could hardly trail herself about."

Thus, then, were the miserable and intractable sufferings of years, shutting out this poor woman alike from society and employment, put an end to at once by an operation whose best recommendation is its simplicity and its success.

Leeds.

CASE OF HIGH TEMPERATURE IN RHEUMATIC FEVER TREATED WITH THE WET PACK.

By T. CARLETON RAILTON, M.B. LOND., F.R.C.S. ENG.

ELLEN G——, aged twenty, a housemaid, after having complained for two days of not feeling very well, and of pain in her right wrist, was sent to bed on June 25th, 1874, with all the symptoms of rheumatic fever. The pulse was 100, full and soft; both wrists were painful, and slightly swollen, and there was a copious perspiration, having the usual sour odour. The only treatment adopted at this stage was an opiate mixture to relieve the pain, together with the wrapping up of the affected joints in cotton wadding.

On June 26th the pain in the wrists had become more severe, and was accompanied by pain in one knee and in the back. The temperature taken at 10 A.M., in the axilla, was 102° F. Upon auscultating the chest, a mitral regurgitant murmur, soft in character, was perceived; this was treated by the application of one of Rigollot's mustard leaves over the cardiac region, followed by a constant succession of hot linseed-meal poultices.

June 28th.—The pain in the joints, although diminished in the wrists, had become intensified elsewhere, both knees and one ankle being somewhat swollen. Since the 26th the mustard leaves had been reapplied to the chest as frequently as the patient could bear them.

29th.—On being raised up in bed the patient fainted. The pulse still remained 100, but was very soft and compressible. A freshly prepared infusion of digitalis was ordered, together with certain fixed quantities of nourishment and stimulants at frequent intervals.

30th.—The faintness still continued; other symptoms remained the same.

July 1st.—The same symptoms. Temperature at 7 P.M. 103°. At night she began to ramble in her speech. Cold water cloths were kept constantly applied to her head.

2nd.—Rambling continued. Ice to the head.

3rd.—The rambling had turned to loud delirium, the carotids beating fiercely. The temperature at 4.30 P.M. being found to reach 105·7°, the wet pack was resorted to for the first time. A sheet was soaked in iced water and wrung out; the patient was then enveloped in it from head to foot for the space of half an hour, at the end of which period the thermometer showed an abatement of the temperature to 104°, and so far from appearing exhausted by the process the patient appeared considerably improved; the pulse, though still 100, being firmer, while the violent excitement had given way to a comparatively sound sleep. At 11 o'clock the same evening these good effects had passed off, but the temperature still continued at 104°. The wet pack was applied for the second time in the same way as before, with the result of a descent in temperature to 102° and a tolerably quiet night.

4th.—At 10 A.M. the temperature had again risen to 104·5°, and the patient still continued to ramble. After another half hour in the wet pack, the temperature went down to 101·8°; pulse 100; respiration 28. At 11 P.M. I was hastily sent for. The woman appeared to be sinking and almost unconscious; the pulse was very rapid and weak; the temperature was 104·2°. So great was the bodily prostration that I feared to have her lifted from the bed to the couch upon which the wet sheet had been spread, therefore, as an alternative plan, a large bath towel wrung out of iced water was tucked around her as far as possible without disturbing her. Stimulants and beef-tea were constantly administered. At the end of five minutes the towel was changed for a freshly-iced one, and in five minutes more a third was applied, the whole process thus occupying the space of a quarter of an hour, with the result of a descent in temperature to 103·4°, and a pulse much firmer and slower.

5th.—At 2 A.M. the bath towels were again applied as before to the front of the body, reducing the temperature to 102°. At 4 A.M. the process was repeated, but without observation as to the temperature. The patient was afterwards sponged over slowly with iced water from head to foot at intervals of an hour until 11 A.M., and by this means the temperature was maintained at 102°. The pulse (102) at this time was very much firmer, and the patient appeared calmer and more collected than she had been during the previous five days. The ice to the head was discontinued. The sponging was renewed for a quarter of an hour at 7 P.M., and also at 11.45 P.M., at which time the temperature was found to be 101·4°.

6th.—At 9 A.M. the patient, though still suffering considerable pain in some of her joints, was perfectly composed, and the marked depression from which she had previously suffered had passed off. Her pulse was 92; the temperature 100·4°.

Since the last date she gradually but slowly returned to comparative health, with but one slight relapse of the affection of the joints, unaccompanied by any great increase of temperature. The period of convalescence was naturally prolonged by the existence of the valvular disease of the heart, and by a very severe bedsore, but at the present time she is well enough to perform all the ordinary duties of her station.

In this brief record of (what was to me) a most interesting case, I have designedly omitted many details, as not bearing directly upon the object I have had in view in reporting it. It is evident that the application of cold to the body in cases where the temperature of the blood rises to a pitch at which it imperils the action of the heart (threatens its paralysis in fact), is as justifiable a course in rheumatic fever as in any other.

Old Trafford, Manchester.

TWO CASES OF THORACIC ANEURISM.

By FREDERICK ENSOR, M.R.C.S.,
SURGEON TO THE PROVINCIAL HOSPITAL, PORT ELIZABETH, SOUTH AFRICA.

To the physician who is alive to the insidious nature of thoracic aneurism, no cases cause more anxiety than those which exhibit symptoms of this grave organic lesion. I imagine in every hospital of seaport towns "cases" from the shipping are admitted which often puzzle the keenest and most painstaking observer. Men who are dissatisfied with their ship or captain, or who are attracted by diamond-fields or stories from gold-fields, will try every ruse to keep in hospital, but directly the vessel is out of sight their recovery is marvellously quick. When a man tells the usual tale of having pains here and there, and at the same time his pulse and temperature are fairly normal, or perhaps the former a little quickened by his "intent to deceive," and there be no marked symptoms of rheumatism, or expression of malaria or syphilis, you cannot but suspect him of malingering; and yet he may be the subject of grave internal mischief, causing immediate danger to life. I always like to give a man the benefit of the doubt, and watch and wait for a few days rather than act on a diagnosis which one may have cause to regret.

From manuscript notes of a clinical lecture on a case of aneurism of the aorta, by Dr. Todd, in 1855, I copy the following: "When patients above the age of thirty come to consult you about pains extending over the shoulders and chest, an aneurism should always be suspected." All King's men who had the good fortune to study disease at the bedside under that master in diagnosis, Dr. Todd, will coincide with me that it was a privilege and a treat to see him grapple with a difficult case of heart disease or aneurism: the repeated careful examination; the appreciation of, to us students, trifling symptoms; the patient watching of the man as he perhaps sat on his bedside; and the feeling that the *vim*, or vital force, or mind, as his disciple, Dr. Beale, would say, was stirring the depth and breadth of his "cerebral bioplasm," as it strove to solve the "enigma of life" in question, had a good effect on the class, and I dare say has made not a few strive to follow in the steps of so great a teacher.

The aid to diagnosis, which I quote from the clinical lecture, has been well illustrated in two cases which have come under my observation in this hospital; one occurred some two years ago, the other a few days since. As necessity of care in diagnosis is the only point I wish to lay stress on in these cases, I will not enter into much detail.

The first case was that of a sailor—I write from memory. He was a tall man, rather thin, aged about forty, and was admitted complaining of pain, not very severe, of a neuralgic character, in the spine and about the chest. The captain "thought he was scheming." He had been under medical treatment for same symptoms; no diagnosis had been distinctly given; he was suspected of trying to get rid of his ship.

I examined him several times and got at no positive symptoms to guide me, and yet there was something in his look which told of suffering, and made one feel that the man's pains were not imaginary. He had been in hospital about a week when I detected a prolonged sound, not amounting to a "bruit," at the back, between the shoulders. I gave a guarded diagnosis of aneurism of the thoracic aorta. A few days after, in the act of lighting his pipe, he fell dead at his bedside, and the post-mortem examination disclosed a circumscribed aneurism of the descending aorta, which, having eroded two or three of the vertebræ, had given way and filled the left pleura with blood. When men are admitted who, without a doubt, are "sea lawyers," I generally order a few doses of sulphate of magnesia, flavoured with tincture of assafœtida, and I find that they soon ask permission to leave the house. In the post-mortem room I felt glad I had not ordered the "stimulant mixture," as we term it, in the above case.

The second case, which occurred a few days ago, was the following:—A tall, thin, big-boned man, formerly a private in the German Legion, was admitted complaining of pain lancinating in the line of the intercostal nerves and lower part of the chest. No murmur at base or apex of the heart. Pulse even in both radials; no dulness over the middle of the sternum; no marked dyspnœa. The only thing I could detect was a limited dulness about the middle of the left lung, with rather harsh respiratory sounds; no cough or expectoration; pulse and temperature normal. The man was, nevertheless, conscious of something serious the matter with him; his eyes were particularly bright, the sclerotic pearly and clear.

At first I thought he was a dyspeptic "loafer" trying to remain in hospital. A thought of tubercle being laid down crossed my mind, but the pulse and temperature were against this idea. I remarked to the house-surgeon, "that it was not improbable we should find an aneurism in this case." After a careful examination, I could come to no conclusion, refused to commit myself to a diagnosis, and simply ordered him to remain in bed. No medicine was prescribed.

Two days after this, while engaged in an operation for crushed foot, the nurse entered the room, saying the German was "in a fit," as she called it. As soon as the operation was completed, on proceeding to the ward, I saw the poor fellow lying in bed, quite dead, with extreme pallor on his face. He had evidently died in a faint. The following day a post-mortem examination revealed an aneurism about the size of a turkey's egg in the descending aorta, which had eroded the seventh and eighth vertebræ, and had burst, filling the pleura with blood. The heart was small, and thin and pale in its muscular structure. The aortic valves were somewhat thickened, but not incomplete; the mitral valve was also thickened a little, but, I imagine, had been equal to its office, or we should have had more dyspnœa. Both lungs were hyperæmic, the left slightly consolidated at its contact with the aneurism.

These two cases illustrate well how cautious one should be in coming to a conclusion in a case. A harsh judgment, a wrong diagnosis followed by harmful treatment, would always be a matter of extreme regret to the physician, and, in some cases, might give rise to much social distress. Better that a scheming patient should impose on his doctor for a few days than that a poor fellow with thoracic aneurism should be hurried to his end by active treatment on a wrong diagnosis.

In Trousseau's "Clinical Medicine," vol. i., p. 597, is a case well illustrating the point I wish to impress in these few remarks.

CASE OF
DIABETES MELLITUS OR GLYCOHÆMIA.

By Surgeon JOHN C. LUCAS,
H.M. BOMBAY ARMY, IN MEDICAL CHARGE H.M. 18TH REGIMENT, N.I., CAMP DEESA.

Private Punchum Lalla, aged forty; service twenty years; married, but no family. The patient, a man of average height and fair intelligence, says that he enjoyed excellent health until about eighteen months ago, when, serving with the regiment at Rajcote, after repeated attacks of fever and ague, he observed that he began to pass large quantities of urine, and that the calls to micturition had been increasing in frequency, and also thirst had been in proportion excessive. His appetite has been gradually augmenting, and now he describes it to be ravenous. He has been rapidly losing flesh; from being a strong, muscular man, he is reduced almost to a skeleton. He complains of dimness of vision and near-sightedness, which he says have been steadily advancing. He admits having contracted a syphilitic sore on the genitals about sixteen years ago, and which was followed by laryngeal and cutaneous symptoms of constitutional syphilis. Habits temperate; does not remember any severe injury to the head. No information can be derived in regard to his hereditary history.

Present condition.—August 26th, 1875: Patient is greatly emaciated, with spare flabby muscles, height 5 ft. 5½ in.; weight, without clothing and on empty stomach, 84 lb. Aspect anæmic; expression of face anxious and careworn; appearance of the eyelids not unlike that of a myopic individual. Skin very dry, and feels like parchment, and indicating want of action of the sudoriparous, but not of the sebaceous follicles, as there is a shining or glistening aspect of the skin. Temperature at the axilla 96 8°. On the scrotum and penis there are cicatrices of syphilitic ulcers. There is some slight hyperæsthesia all over the body. Physical examination of the chest elicits nothing abnormal with regard to these, though the action of the heart is, of course, feeble; pulse in the sitting posture 74 per minute, small, and somewhat hard. Complains of some uneasiness (but not actual pain) in the lumbar region; quantity of urine passed in twenty-four hours 130 ounces, of faintly acid reaction, specific gravity 1040; the usual tests show abundance of sugar. Testes small and atrophied, and there is want of sexual desire. Mouth and fauces dry; tongue pale and furred; thirst intense; appetite large; bowels irregular; no pain or vomiting after food. Hepatic and splenic dulness normal. Memory to a certain extent failing; sleep disturbed by dreams; sometimes has shooting pains in different parts of the body. The ophthalmoscopic examination points to some atrophy of the left optic disc; direct illumination (without the object lens) proves the myopia.

The treatment ordered was dietetic. Mutton 2 lb, made into broth, flour bread 1 lb., milk one pint, brown sugar ½ lb., and four eggs. He was also to take two drachms of cod-liver oil and two grains of sulphate of iron twice a day; and advised to take drinks acidulated with dilute sulphuric acid and refrain from taking water as much as possible.

* In addition, diaphoretic treatment.

Remarks.—The treatment resorted to in this case has been considerably varied. Both sugar and starch were for a time allowed and withheld. The favourite remedies, opium and creasote, were in their turn tried, but had no decisive effect on the polyuria, as will be seen from the above columns. On Sept. 8th the saccharine and starchy constituents in the diet were altogether omitted, and, in addition to the cod-liver oil and iron, three minims of creasote, with a grain of opium, in pill, were ordered; then on the 16th these latter drugs were stopped, and the patient was allowed as much skim milk as he could take. Lastly, on the 24th I resolved to act upon the skin, and therefore the patient was ordered a warm bath daily, and half a grain of ipecacuanha, with a grain of opium, twice a day.

From this case it will be seen that the sugar in the diet did not produce any ill-consequences, and as far as this case is concerned the skim-milk plan of Dr. Donkin of Durham did not prove of much avail. During the above period the urine always continued saccharine, and the specific gravity fluctuated with the dilution—i.e., when the total quantity was less, the specific gravity rose in a corresponding ratio, and *vice versâ*. I believe the actual quantity of sugar excreted in a fixed number of hours remained much about the same.

The man continued losing weight (on an average from a pound and a half to two pounds weekly), but as yet there is no evidence of deposition of tubercle in the lungs, so that the patient will in all probability sink from asthenia rather than supervention of phthisis.

At the "invaliding," which is shortly to take place, the man will be recommended to take his discharge, and as he will leave the station for his native place, there will, unfortunately, be no opportunity afforded to learn the further progress of his case, or an autopsy in the event of a fatal issue.

LARGE HYDATID TUMOUR OF LIVER AND RIGHT PLEURA; PUNCTURE, FOLLOWED BY COLLAPSE, PERITONITIS, AND SUPPURATION WITHIN THE MOTHER CYST; FREE OPENING, PERMITTING DISCHARGE OF NUMEROUS HYDATID CYSTS FROM TIME TO TIME; PLEURO-PNEUMONIA OF RIGHT SIDE; DEATH; AUTOPSY.

(Under the care of Dr. Andrew.)

For the following notes we are indebted to Vincent Harris, M.B. Lond., house-physician.

Ellen M——, aged thirty-nine years, an itinerant fruit-vendor, was admitted into Mary ward on Sept. 3rd, 1875. She stated that she had always been healthy and strong up to her last confinement five years ago, since which time occasional pains in the right side had somewhat troubled her, but she had been able to do her work fairly. About twelve months before admission she had noticed that there was a swelling rather high up on the right side of her abdomen, and that it had gradually increased. During the past four or five months the pains in the side had become more severe, sometimes enforcing entire cessation from work. Had never been jaundiced.

On admission, the patient was healthy-looking and fairly nourished; complexion sunburnt; conjunctivæ and skin not jaundiced; functions natural; pulse 80. No abnormal pulmonary or cardiac signs. The lower part of the right side of the chest and upper part of the corresponding side of the abdomen were decidedly bulged. The swelling was rather tender on palpation, and presented in its lower part well-marked fluctuation. The liver dulness began about an inch below the right nipple, extending downwards, in the nipple line, to near the level of the umbilicus,—across, on a slightly higher level, to the left hypochondrium and to the right, and backwards to a proportional extent. The surface, as far as could be made out, was smooth, but presented one or two slight irregularities. The urine was light-coloured and acid, of specific gravity 1008, and contained no albumen. The catamenia had been absent for several months. Family history of consumption, but none of tumour.

An hydatid tumour of the liver having been diagnosed, it was decided that it should be tapped after the patient had been put in as good a state of health as possible by rest in bed. Accordingly on Sept. 11th a puncture was made, and about an ounce of fluid was with difficulty withdrawn with an aspirator. The fluid was glairy and gelatinous, containing, as far as could be discovered, no hooklets or striated membrane.

On Sept. 13th the note is —"Since the operation the patient has been greatly collapsed, and her nails, nose, and lips are singularly blue. Complains of some pain in her right side at the seat of the puncture, and some tenderness also. The tongue is rather furred on the dorsum. Pulse 108; temperature 99·2°."

For the next few days the patient showed signs of severe peritonitis. Her pulse and temperature rose, her tongue became brown and dry, and the abdomen grew very tender. She lay constantly on her back, with her knees drawn up. Her bowels were very constipated.

On the 16th and 18th she had severe rigors, which were followed on the latter occasion by jaundice, and from the marked evening rise in the temperature, with other symptoms of hectic which followed, suppuration in the hydatid cyst was feared. The jaundice increased for a few days, the urine becoming very dark, of sp. gr. 1022, acid, and containing bile, but no albumen. The pain in the tumour increasing, and the hectic continuing, a large trocar and canula were used on the 23rd to puncture the sac. The fluid which exuded being too gelatinous to pass through the attached tube, the instrument was withdrawn, and dressing forceps were inserted into a free opening previously made. By this means about two or three ounces of glairy, and more or less purulent, fluid were evacuated, and a thick-walled hydatid cyst was removed.

After the operation, as soon as the collapse (which was abnormally severe) had subsided, the patient did fairly well for some time. On Sept. 29th there was a large discharge from the wound (still kept freely open), consisting of a great number of hydatids of all sizes, some whole, but most of them collapsed, of gelatinous fluid and pus. During the next fortnight cysts came away on about eight or nine occasions, and the external swelling decreased in size. On Oct. 8th the patient complained much of cough, and by physical examination the base of the right lung was found to be dull on percussion, with crepitation and rough breathing above the area of dulness. The sputum was pneumonic.

From this time the lung symptoms increased in severity, the patient became more and more cyanotic, and died on Oct. 19th, having been light-headed during the two preceding nights.

There were several discharges of hydatid cysts during the ten days before death. In all it is calculated that fully a hundred cysts were discharged through the opening in the side. The temperature during the whole course of the disease, after the first tapping, was always above normal; it varied from 100° to 103° F., being invariably raised in the evening. The pulse corresponded closely with the temperature. Jaundice appeared on Sept. 19th, as mentioned above, and continued throughout the remainder of the case.

The treatment consisted in perfect rest, light food easy of digestion, and, in the way of drugs, opium to allay pain, to keep the bowels quiet, and to procure sleep, an occasional castor-oil injection being used to relieve the bowels.

Autopsy.—On opening the chest and abdomen the liver was seen to be pushed over to the left side, while in the place of the greater part of its right lobe there was a huge, thick-walled sac, containing fluid. This sac communicated with an hydatid cyst in the right pleural cavity at its back and upper part. The communication was a small hole in diaphragm. Thus, from the second rib to below the umbilicus (as the cyst extended downwards to this point) there was a huge sac containing hydatid cysts, with about four quarts of fluid. The hydatid of the pleura had penetrated for a short distance at one point into the substance of the lung. The lung was collapsed except near the part penetrated, where it was solidified, with a granular appearance on section. The left lung was normal. The heart was not diseased or displaced. The left lobe of the liver was about the size of an ordinary right lobe; the right was about three or four inches broad transversely, and then seemed to spread out as a thin layer of liver substance, soon altogether disappearing on the anterior surface of the hydatid. Gall bladder normal. The liver substance was pale, with rounded edge and amyloid reaction. The spleen was slightly enlarged and amyloid. The peritoneum about the cyst was thickened at the seat of old adhesions, and there was also recent lymph about it. The surface of the left kidney was smooth, with one scar like that of an old infarct; otherwise normal. The right was adherent to under surface of cyst of liver, granular and tough. Cortical substance diminished. Several small cysts on surface. Intestines and mesenteric glands natural.

WEST LONDON HOSPITAL.

TWO CASES OF INTERNAL URETHROTOMY FOR NARROW, NON-DILATABLE STRICTURES; GOOD RESULTS.

(Under the care of Mr. Teevan.)

The following cases are interesting as showing the efficiency of the operation, the slight annoyance it occasions, and the brief confinement it necessitates.

Case 1.—George G——, a healthy-looking sailor, aged thirty, was admitted into the hospital on Nov. 2nd. The patient stated that six years ago he suffered from a gonorrhœa, for which he was treated with medicines and injections. The complaint degenerated into a gleet, which hung about him for a long time. A year ago he had an attack of retention, which he overcame by hot gin-and-water and severe straining. Three months ago, when at New York, he had another attack, and the surgeon whose advice he sought was not able to pass a catheter till he had anæsthetised him. When he applied to Mr. Teevan six weeks ago he complained of frequent and difficult micturition, and the annoyance of having his "pants" always wet from the dribbling of urine. Examination detected the existence of a tough stricture three-quarters of an inch long, four inches from the meatus externus. There were also three ring strictures of large calibre in the penile urethra. Gradual and continuous dilatation were both fairly tried, but the deep stricture could only be enlarged sufficiently to admit of the passage of a small catheter, and as it was desirable that the patient should be able to introduce a full-sized instrument for himself, he being a sailor, an operation was indicated. Accordingly, on Nov. 2nd, at 3 o'clock p.m., Mr. Teevan passed a catheter staff, and, having proved its position by withdrawing some urine through it, divided the stricture internally from before backwards. Only a few drops of blood were lost; a large metal catheter was introduced, and the water drawn off quite clear, to demonstrate that the calibre of the urethra was re-established, and that there was no hæmorrhage into the bladder. At 10 a.m. the next morning Mr. Noot, the house-surgeon, found the patient had slept well, and that his tongue was clean and moist, and the skin cool. The pulse was 78, and temperature 98·4° F. Micturition was attended with much smarting. On Nov. 5th the patient was up and walking about the ward; the soreness was nearly all gone. No. 20 (Charrière) metal catheter was passed; on the 6th, No. 22 olivary metal bougie; on the 8th, No. 22 conical elastic bougie; and on the 10th, No. 20 silver catheter. The patient left the hospital the same day quite well in all respects. He has since learned to pass a full-sized elastic bougie with ease for himself.

Case 2.—Robert P——, a thin and rather haggard-looking labourer, aged thirty, applied as an out-patient on Oct. 9th. He stated that he had never had gonorrhœa, gleet, or syphilis; but that fifteen years ago he was rolled over and kicked in a scuffle, and that his urine ran away from him. For the last ten years he has passed a very bad stream of urine, and a year ago was attacked with retention, for which he went to St. Thomas's Hospital. No instrument could be introduced, but he was relieved by a hot bath. At the present time the patient is troubled with difficult micturition, accompanied by much straining. Examination detected a very tough thick stricture, half an inch long, three and a half inches from the meatus externus. Gradual dilatation was tried, but no progress was made, and only the smallest elastic catheter could be introduced. On the 2nd of November the patient entered the hospital, and at 3.30 P.M. the same day Mr. Teevan divided the strictures, internally, from before backwards, having first demonstrated that the catheter-staff was in the bladder by withdrawing some urine through it. About a teaspoonful of blood was lost. A large metal catheter was passed, to prove that the calibre of the urethra was restored. The water which flowed through from the instrument was quite clear. At 10 o'clock the next morning Mr. Noot found the patient comfortable; tongue clean; skin cool; pulse 90; temperature 98 4°. On the 5th, No. 20 metal catheter was passed; on the 6th, No. 22 conical metal bougie; on the 8th, No. 22 conical elastic bougie; and on the 10th, No. 20 silver catheter. The patient left the hospital the same day in all respects quite well. He can now pass a full-sized elastic bougie for himself.

Mr. Teevan observed that he considered no operation upon a passable stricture justifiable unless milder measures had been tried and found wanting. In the cases under notice, dilatation had been employed without success, because the strictures were so tough as to be incapable of being dilated beyond allowing a small catheter to pass. An operation was therefore indicated, and he had selected internal urethrotomy as most appropriate for these particular cases. The great point in the operation was to prove, before cutting, that the catheter-staff or guide had really been passed into the bladder, which he had done by withdrawing urine through it. Provided this, the one thing needful, were done, it mattered but little whether the stricture was divided from before backwards or *vice versâ*. Some surgeons had an objection to the division from before backwards, but the objection could not be maintained, and had arisen from the fact that formerly the division from before backwards had been performed without demonstrating that the instrument was really in the urethra. Hence it was that mistakes had arisen from the urethrotome having been passed into a false passage or the rectum, and thus it was that the principle of division from before backwards had been saddled with the errors of a faulty execution, which really formed no part of the operation. In internal urethrotomy the prostate and neck of the bladder were not touched. This was a most important point, for whatever hæmorrhage ensued it must make its exit at the external meatus, as it could not gravitate backwards into the bladder, its neck being firmly closed. If a blood-clot formed in the bladder a stone might result. Now, this could not occur in internal urethrotomy, but it might do so when a stricture was forcibly dilated, for Civiale had pointed out that in that operation the neck of the bladder might be injured, and allow of hæmorrhage into the organ, and he had been informed of a case where, after the operation of immediate dilatation, a stone had formed on a blood-clot. Of all operations for stricture internal urethrotomy was attended with the least risk. Its twin sister—subcutaneous section—excelled it so far as regards the certainty of ensuring a thorough division of a stricture, but it was not always applicable.

DORSET COUNTY HOSPITAL.

EXTENSIVE INCISED WOUND THROUGH THE CALF OF THE LEG; IMPORTANT AND SATISFACTORY USE OF THE CARBOLISED CATGUT SUTURES.

(Under the care of Mr. John Tudor.)

B. P——, labourer, aged twenty-three, was admitted into the hospital late on the night of August 23rd, 1875, with a semilunar incised wound through the calf of the leg, about ten or eleven inches in length, the course of the wound being in a direction from below upwards, having very much the appearance of a posterior flap in an ordinary amputation. The soleus and gastrocnemius muscles were cut through, and part of the flexor longus pollicis. The accident occurred in the harvest-field, owing to the man running across a scythe whilst chasing a rabbit at full speed.

In consequence of the upward course of the wound, no important vessels were injured. One which bled rather freely was ligatured, and another twisted. The chief difficulty presenting itself was the retraction of the muscles, even to the extent of several inches when the knee was fully flexed, rendering it impossible to secure them in the same sutures as the skin. Taking this into consideration, the muscles were separately brought together by means of carbolised catgut. The sutures were passed, about an inch from their margins, through the entire thickness of the muscles, and tightly secured, thus bringing the opposed surfaces together firmly. Their ends were then cut short off.

The skin was brought together by twelve silver wires; the wound was covered with carbolised oil, lint, and tow; the knee was flexed and secured by a bandage passed over the foot and made fast to a belt around the waist, the limb being then raised and placed upon pillows, resting on its outside. The progress of the case was very satisfactory, the wound healing chiefly by first intention. At the end of three weeks the patient was convalescent and able to walk quite comfortably, and was discharged Sept. 23rd, a month after his admission.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

At the ordinary meeting of this Society, on the 26th ult., the chair was taken by the President, Sir William Jenner, Bart. The chief feature of the evening was a case of acute cancer of the liver, with pyrexia, related by Dr. Murchison, which led to an interesting although somewhat desultory discussion, commencing with the question of pyrexia in cancer and terminating with that of dropsy from venous obstruction. Mr. Lawson showed two interesting cases in which he had removed tumours from the orbit.

Dr. Murchison read notes of two fatal cases of Acute Pyelitis and Nephritis, apparently consequent on Gonorrhœa. These cases occurred several years ago at the London Fever Hospital, and illustrated a mode of fatal termination of gonorrhœa which, although tacitly acknowledged as probable, had yet been but seldom recorded. In "Chelius's System of Surgery" it is stated that John Hunter was of opinion that the irritation of gonorrhœa was sometimes propagated to the kidneys, but beyond that statement Dr. Murchison had been unable to find any records of such cases. Dr. G. Johnson had informed him that he had either met with or read of such a termination of gonorrhœa. The first case was that of a grocer's assistant, twenty-eight years of age, who was admitted into the Fever Hospital on June 4th, 1865, in a state of profound coma, with low muttering delirium and a dry, brown tongue. There was no eruption; the temperature was not taken, and no urine could be obtained. There were moist sounds at the back of each lung. The man died three hours after admission, and after his death it was learnt that he had been for some time suffering from gonorrhœa, the cerebral symptoms being of only two days' duration. On post-mortem examination the entire length of the urinary tract was intensely inflamed and bathed in pus, that in the ureters being thick and yellow; and both kidneys were deeply engorged, in the first stage of acute nephritis. There was no old renal disease and no dropsy. There was incipient lobular pneumonia in the lower lobes of the lungs, which were much congested. The brain was not examined. The second case was that of a lady's maid twenty-five years of age, who was admitted into the same hospital on Jan. 31st, 1866, in a state of unconsciousness, with dusky face and laboured breathing. There was convergent strabismus, a well-marked cerebral macula; no rash. There is no record of the pulse or temperature in this case. There was hypostatic congestion of the lungs, and the patient died on Feb. 2nd, never having regained consciousness. Death was preceded by two convulsive seizures. After death it was learnt that she had been apparently well up to the day before admission, when she had travelled from Paris to London. Arriving in London, she made a good meal, and was subsequently attacked with convulsions, and then brought to the hospital in a state of coma. There was found hyperæmia of the membranes and substance of the brain; no tubercle in the lungs, which were congested; the kidneys were large, smooth, and almost black from the large amount of blood they contained; the ureters and bladder contained a large quantity of pus, and the whole genito-urinary tract was intensely injected.—Dr. Greenhow said that he was reminded of a somewhat similar case which he saw when he was a student at Edinburgh. He was present at the post-mortem examination of a man who had died in a state of coma of thirty-six hours' duration. He was supposed to have been poisoned, but he was the subject of gonorrhœa, for which he had been taking copaiba and using injections. Sir William Newbiggin at the time attributed the symptoms to "cerebral metastasis" from gonorrhœa checked by treatment. — Sir William Jenner asked if it was quite certain that the female patient had gonorrhœa.—Dr. Murchison replied that there was no history to be obtained on this point, but the post-mortem appearances in her case were similar to those in the male patient. In answer to Mr. B. Hill, he also stated that the duration of the gonorrhœa in the male patient was not defined; it had existed for some time. He further stated, in reply to a question put to him by Sir William Jenner, that the man had been under treatment for gonorrhœa, and he could not say that he had taken cantharides. Opposed to the view of the inflammation of the kidney being primary was the fact of the distension of the passages with pus, the ureters appearing as thick cords. Although such extension of inflammation was commonly stated in text-books, he had never come across any others. — Sir William Jenner thought the interest lay in the extension of the inflammatory mischief to the finer structures. Such cases must be rare, else among the many surgeons present there must have been some who had met with them.

Dr. Murchison then read notes of a case of Acute Cancer of the Liver, with Pyrexia, in a man aged twenty-four, which, he said, illustrated a clinical fact of some importance—namely, that the temperature in certain cases of cancer may be elevated. Not much is known as to the range of temperature in cancer. Wunderlich says a high temperature in such cases is usually dependent on complications; a statement confirmed by Dr. Woodman, who adds that the rise of temperature in cancer is rarely above normal limits. The patient was a carpenter, who, six months before his admission (Nov. 6th) into hospital, strained himself, and attributed to this strain a swelling with tenderness of the left testicle. There was no history of malignant disease in his family. Six weeks before admission he began to have pain in the right side of the abdomen, and some enlargement of the liver began to be noticed. This enlargement progressed rapidly, without any rigors, but with profuse night-sweats and much emaciation. On admission, the temperature was 101·3°. He complained of pain in the hepatic region, which was bulged, the liver itself reaching as low as the pelvic brim, and, above, its percussion-limit was about an inch and a half above the nipple. The surface of the liver was smooth, tense, and tender. There was slight jaundice; no ascites. Specific gravity of urine 1018; contained a trace of albumen. There was slight cough. A little sibilus audible over both lungs at back. Pulse 120. The left testicle was twice the size of the right; hard, but not tender. The liver continued to enlarge; he had frequent attacks of vomiting; the jaundice increased; and death took place after several days' delirium, and on one occasion a decided rigor followed by heat and dry skin. The complete record of the temperature was unfortunately lost; but Dr. Murchison gave the following figures on the first few days of observation:—Nov. 6th: Evening, 101·2°. 7th: Morning, 101·1°; evening, 103°. 8th: Morning, 99°; evening, 101·4°. 9th: Morning, 98·5°; evening, 101·2°. 10th: Morning, 99°; evening, 100°. 11th: Morning, 100°; evening, 103°. The liver was found to be greatly enlarged, measuring 12½ inches vertically; and its entire substance was studded with masses of vascular cancer, varying in size from that of pea to that of a chesnut, not softened, but exuding a milky juice filled with large nucleated cells. There was no recent peritonitis, and no inflammatory change in the liver-tissue that remained. A chain of cancerous glands passed up the abdomen in the region of the left kidney; and the left testicle was also infiltrated with cancer. Both lungs presented similar masses of new growth; but there was no sign of recent inflammation in them. The heart was healthy. The case was an obscure one on account of the high temperature, the age of the patient, the history of previous injury to the testicle, supervention of the cerebral symptoms, and of a rigor shortly before death. The diagnosis was that the case was one of pyæmic inflammation of the liver; and the case was of interest in showing how closely a rapidly evolving cancer without any inflammation could simulate pyæmia. — Sir William Jenner asked whether the hepatic tissue between the masses of cancer showed any evidence of inflammation.—Dr. Murchison replied that it was injected, but showed no inflammatory exudation or pyæmic deposit. It had been carefully examined with the microscope. In answer to Dr. Southey he said the testicle was cancerous, and pointed out that it was curious that although that organ was the first affected, the disease had remained stationary there, spreading up by the lumbar and retro-peritoneal glands to the liver.—Dr. Moxon inquired whether the portal veins had been examined. He referred to a case which he had published in the *Medical Times and Gazette* for 1873 (vol. i.) It was the case of a gentleman, twenty-six years of age, who had during life symptoms resembling suppuration of the liver, the temperature rising several times to 102·5°, with rigors and night-sweats. After death the liver was invaded with cancer, and the branches of the portal vein were stuffed with masses of cancer. The liver-tissue between the cancer nodules was swollen and pinkish. He compared it at the time to the union of chlorine and hydrogen as producing heat similar to the union of oxygen and hydrogen, believing simply that pyrexia was an acute phenomenon produced by changes different in kind but equally rapid in progress.—Dr. Murchison replied that there was nothing observed in the larger veins.—Dr. Southey had met with a similar case in which the portal vein was invaded. He thought that in all rapidly growing cancers the chemical changes produced must be varied, and give rise to pyrexia.—Dr. Murchison inquired whether there was any ascites present in the cases mentioned by Drs. Moxon and Southey. No doubt pyrexia might be expected to occur in rapidly spreading cancer, but it had not been so recorded. — Sir William Jenner said that in one of the most rapid cases of cancer he had witnessed, that of a boy, who died a fortnight after the appearance of a tumour in the abdomen, there was no marked elevation of temperature. The cancer was disseminated throughout the pleura and peritoneum, infiltrating the intestinal walls.—Dr. Moxon said there was no ascites present in his case, although the portal vein was so obstructed, but he was not sure whether venous obstruction always led to dropsy. Thus in a case which he brought before the Pathological Society, in which the coronary sinus was entirely closed by a hydatid tumour, the blood finding its way into the auricle by dilated Thebesian foramina; there was no hydro-pericardium. Another case which he brought before the same Society presented complete obliteration of the sinuses of the dura mater by inflammatory growth without there being any effusion. He had seen several cases of uterine cancer in which the veins of the lower limbs were completely plugged without any œdema of the feet.—Mr. Brudenell Carter referred to a case brought before the Clinical Society last session by Mr. Hutchinson, in which there was obliteration of the ophthalmic vein without any swelling of the optic disc.—Mr. Callender asked Dr. Moxon how much of the coronary sinus and in what part of its course was it obliterated?—Dr. Moxon replied that the obliteration took place about one inch from the auricle.—Sir William Jenner said that if the blood were prevented flowing in one direction it must find an outlet somewhere.—Dr. Moxon wished to draw attention to the fact that there does occur blocking of the veins, as the portal, without there being dropsy; so that absence of ascites was no evidence against implication of the portal vein.

Mr. Berkeley Hill made a few remarks on a case of Amputation at the Hip-joint for Fibro-plastic Tumour. The tumour, which was shown at the Pathological Society by Mr. Godlee, involved the whole femur and the femoral vessels. This necessitated making the anterior flap wholly of skin. The flap sloughed, and the patient made a slow recovery, many hundreds of skin-grafts being employed to cover the large granulating surface. The operation was performed on August 12th, and he brought the patient to show the result of the operation. The growth was a round-celled sarcoma.—Mr. Callender remarked that since the introduction of the abdominal tourniquet the old method of performing amputation at the hip by transfixion had fallen into disuse. The plan he preferred was to form an anterior flap, and then to divide the femoral vessels by a clean vertical incision, by which the danger of splitting them was avoided. When this was done, and care taken in making the flap to preserve the branches supplying it, no sloughing followed. He wished to know the *rationale* of the employment of so many grafts in the present case.—Mr. Hill replied that the size and extent of the tumour had obliged him to make the flap by dissecting off the skin from the surface of the tumour; and no doubt he had cut through the branches referred to. He was sure more than a hundred grafts had been used; but when it was remembered what a large surface there was to be covered, including the acetabulum, and that the grafts were made on many occasions, this number was not surprising. The cicatrix obtained was very supple, and proved that many of the grafts had taken.

Mr. Geo. Lawson exhibited two patients from each of whom he had removed a Tumour of the Orbit. They were essentially different, but each presented points of great clinical interest. The first case was that of an elderly woman who was admitted into the Middlesex Hospital, with a large melanotic tumour involving the eye and filling up the whole orbit. This growth Mr. Lawson removed, and then applied the chloride of zinc paste, and in such a manner that he succeeded in saving the upper eyelid. One of the great disadvantages, he remarked, of the use of the chloride of zinc in such cases had been that, owing to the running of the paste into the cellular tissue of the eyelids, both lids had been destroyed by it. The plan which he now adopts, when practicable, is the following:—After the eye and tumour have been excised, pressure is made in the orbit until all bleeding has ceased. The mouth of the conjunctival bag, from which the globe has been enucleated, is now to be held open with two pairs of forceps, whilst the paste, spread on small strips of lint, is plastered round the sides of the orbit. A small piece of cotton-wool is next introduced to keep the strips of lint *in situ*, and the mouth of the conjunctival bag is closed over the whole by a single continued suture. A layer of lint is then placed over the conjunctiva, and upon this the lids are closed and kept in position with a compress of lint and a roller. The patient progressed well, had suffered no pain, and had no recurrence of the disease since she left the hospital on the 25th May. In the second patient Mr. Lawson removed a tumour from within the orbit, without inflicting any injury on the eye. The growth occupied the floor of the orbit, and seemed to spring from the periosteum, far back in the orbit. It was about the size of half a walnut, much flattened when it was pressed between the eye and the orbit, but rounded at its free external border. The specimen was examined by Dr. Coupland, who pronounced it to be a lymphoma.—Dr. Murchison inquired if the first case related by Mr. Lawson was a spindle-celled sarcoma. In reference to this he referred to a case (Path. Trans., vol. xxiv.) in which a spindle-celled sarcoma recurred in the liver, and led to the patient's death eleven years after removal of the primary growth from the orbit.—Mr. Brudenell Carter wished to know whether Mr. Lawson advocated this method for tumours external to the eyeball as well as for intraocular growths. In one case in which he had extirpated a sarcoma of the orbit by means of caustics there was no recurrence, but an unsightly cavity was left. In this case the growth seemed to spring from the periosteum on the inner side of the orbit; and, under such conditions, he feared Mr. Lawson's plan would be inapplicable. The second case related by Mr. Lawson reminded him of a patient, nineteen years of age, in whom the right orbit was filled by a growth pushing forward the eyeball. The eyeball was enlarged, and the eyelids and eyelashes were hypertrophied. The growth was congenital, and had grown rapidly up to the third or fourth year, and then advanced but slowly. He made a long incision along the lower margin of the orbit, and removed a large growth, which was pronounced to be a degenerated nævus. The deformity was much relieved by the operation, and, with the exception of the larger size of the lids and of the eyeball, there was but little difference seen in the two orbits. Two years after the patient returned with the eye again projecting, and the operation being repeated, a similar growth was removed, on this occasion from above the globe. This operation was followed by erysipelas and suppuration, and now the eye has fully receded. Very probably Mr. Lawson would have recurrence of the growth in his case.—Mr. Lawson, in reply, said that those cases only were fitted for treatment by means of the zinc paste in which a bag of conjunctiva could be left behind so as to receive strips of lint bearing the paste.

Mr. Brudenell Carter then introduced a patient on whom he had performed his new operation of iridectomy. (See page 561.) The case was one in which the effects of the operation could be well seen, the patient having green irides. The artificial pupil was made in an external direction.

The Society then adjourned.

MEDICAL SOCIETY OF LONDON.

At a meeting held on the 22nd ult., Dr. Routh, President, in the chair, Mr. Francis Mason exhibited a most interesting case of Tumour of the Palate. The patient, who was thirty-four years of age, and whose voice was not impaired, had remarked thirteen years ago a small growth on the hard palate. This increased in size, and was, previously to the man being seen by Mr. Mason, the seat of hæmorrhage, which was reproduced profusely on examination. An ulcer and cavity at the back of the tumour were discovered, and the bleeding was treated with perchloride of iron on admission into St. Thomas's Hospital. Mr. Mason said that the tumour had perceptibly diminished, and that he thought it was of a cystic character. His object in bringing the patient forward was to inquire if similar cases had been seen, as he thought this kind of tumour to be rare, and he wished to hear any suggestions as to operative interference. —Mr. Adams dilated on the rarity of tumours of the hard palate, but related a case of his own similar to the one brought before the Society, in which he had removed the growth with ease, though he had anticipated considerable difficulty, and he recommended removal in Mr. Mason's case, the tumour being, in his opinion, fibroid and non-malignant.

Dr. Thorowgood then showed the Cirrhosed Liver of a Child ten years of age, who had died after exhibiting abdominal enlargement and blood in the stools. He dwelt on the youth of the patient, and on the absence of any alcoholic stimulation.—To a question by Dr. Leared, inquiring if the child came of intemperate parents, Dr. Thorowgood replied in the negative. — Mr. Adams and Dr. Crisp made a few remarks, the latter speaker alluding to the large quantity of spirits given to children by poor parents.

Dr. Thorowgood exhibited an Inhaler invented by Mr. Carrick, of Glasgow, the use of which was ably demonstrated by the inventor.

Dr. Brunton then read a paper "On the Rational Treatment of Common Tapeworm." After stating the varieties met with in this country, and mentioning the anomalous symptoms to which they give rise (their very anomaly, he remarked, affording a clue to the diagnosis), he stated that the chief points to be observed in the treatment were: a preliminary starvation of twenty-four hours, and the administration of a combination of kamala and male fern—namely, two drachms of kamala to be rubbed up with a little gum-and-water till an emulsion is formed, and then two drachms of oil of male fern to be added, and the whole triturated in a mortar, with a gradual addition of water till a three-ounce mixture is formed, of which half is to be given at bedtime, and the remainder four hours later. This he had never known to fail. He insisted on the quality of the drugs being good, and spoke of the after-treatment by tonics.—In the discussion which followed, Dr. Fothergill said he thought the way in which drugs were administered in these cases was an important point.—Dr. Leared said he himself first introduced kamala into this country, which he first thought had a mechanical effect, but has since found the tincture to be as powerful as the powder.—Dr. Rogers spoke of the inferior quality of the drugs supplied to hospitals and dispensaries.—Dr. Crisp thought turpentine in large doses to be very effective, and did not think worms were ever introduced into the system by vegetables.—Dr. Cook had used the areca nut with success combined with the male fern.—Dr. Theodore Williams never had much trouble with these cases, and thought the worm did not affect the patient's health to any great degree.—Dr. Farquharson thought the tænia mediocanellata to be more common than the tænia solium. He considered male fern to be very effective by itself, and deprecated the long starvation treatment.—Dr. Godson mentioned the good effect of common salt in these cases.—Dr. Griffith lauded the administration of large doses of iron.—After Dr. Brunton had responded the meeting adjourned.

At a meeting held on November 29th, Dr. Routh, President, in the chair, Dr. Griffith exhibited a case of Hermaphroditism. A discussion followed on the sex of the child, in which the President, after careful examination, considered it a female, as no testes could be found; whilst Mr. Sebastian Wilkinson and Dr. Rogers thought the child to be a male; and Mr. Davy suggested it might be of neuter gender.—Dr. Crisp mentioned a case described by Dr. Clutterbuck similar to one of Prof. Wood's referred to by Mr. S. Wilkinson, and the President appointed Dr. Wiltshire and Mr. Davy to examine the present case, with Dr. Griffith to report thereon.

Dr. Crisp then read a paper "On a Recent Epidemic of Scarlatina, Epidemic Sore-throat, and Erysipelas, which occurred chiefly in June last, in the south-west district of Chelsea," the peculiarity of which, he said, was the large number attacked almost simultaneously, and its general mildness and unfatality as regards scarlatina. A table of 98 cases seen by Dr. Crisp in June was appended, 42 being mild cases of scarlatina (of which only 7 occurred in patients above the age of twenty), and 56 of what he called epidemic sore-throat (only 6 of which were under twenty years of age). The invasion of this latter, he went on to say, was generally sudden, beginning mostly with stiffness at the back of the neck, chills and fever, with depression of power; the tonsils enlarged and inflamed, ordinarily without abrasion or creamy patch; in many cases the glands at the back of the neck were much swollen, there was no eruption or desquamation of cuticle, nor did the white tongue with red tip and raised papillæ exist. One case only, in a lady sixty years of age, proved fatal, and this was from an accidental fall against the bed-post; but in another isolated case, in which abscess formed in the leg, the tracheal obstruction and loss of voice were so formidable that tracheotomy was contemplated. The patients, as in the scarlatinal cases, were all in good circumstances, and very little of the disease, as shown by the reports of the parochial surgeons, was seen among the poorer classes. None of the cases of scarlatina were fatal; they were unusually mild and rarely attended with any kidney complication. The general state of the drains, the opening of the old sewer at the end of Beaufort-street, and the deposit of sewage upon the mud of the river (the disease being confined to an area along the river of about half a mile in length and 500 or 600 yards in breadth) were supposed to have been the chief exciting causes. Erysipelas also prevailed to a great extent; six cases of this disease were seen in infants after vaccination.—In the discussion which followed, Dr. Buchanan thought the method of the spread of erysipelas, sore-throat, &c., required investigation, and mentioned the propagation of erysipelas by vaccination from a subject which showed symptoms of the disease; he also alluded to the spread of scarlet fever through the cream supply, the result of which, however, was as yet inconclusive.—Dr. Theodore Williams supported this view.—Mr. Milton stated that scarlatina had been increasing in severity since the days of Sydenham, although the sewage works in London are more complete at the present than they were at that time. He thought the milk supply not to be the cause of the present outbreak.—Dr. Fothergill, Dr. Farquharson, and Mr. M'Donagh also made a few remarks, and after Dr. Crisp had responded, the meeting adjourned.

Reviews and Notices of Books.

The Diseases of the Heart and of the Aorta. By Thomas Hayden, F.K. & Q.C.P. Dublin: Fannin and Co. 1875.

The treatise which Dr. Hayden has added to the many already existing on diseases of the heart and great vessels is one which has little to fear from rivalry or comparison. Written in a special way, it will have a special value. It outdoes all its compeers, at any rate in size. A thick volume of more than twelve hundred octavo pages is a large work on a special subject. It is, indeed, awkwardly large. Had it been compressed to half or two-thirds of its present size, it would have gained in convenience, and we are not sure that it would have lost in utility. Its size is due to its encyclopædical comprehension of all work on the subject, whether of historical or scientific interest, which sometimes is very small. The facts and statements of other writers, which are reproduced in abstract, constitute probably two-thirds of the work. They are sometimes criticised, but hardly ever digested. They are presented to the reader in equable succession, and, in spite of the many merits of Dr. Hayden's treatise, we are somewhat reminded of the Chinese method of composition of a medical book, according to which the writer invariably describes first what every preceding writer has said upon the subject, and then to the undigested series he adds his own opinion. This is very much what Dr. Hayden has done, but the collection of facts and statements is of great value, and can have been accomplished only by great industry.

The first hundred pages are devoted to the anatomy and physiology of the heart. The additions to our knowledge which have been made by successive workers, from Vesalius to Pettigrew, are detailed. Every important research on both the anatomy and action of the heart is included; the modern theories of the mode of its innervation are given at length. No less than sixteen woodcuts are introduced to illustrate the various theories concerning the time occupied by the various elements of the cardiac action. That accepted by the author is the division in common use in this country.

The mechanism of the sounds of the heart is discussed at great length, and a long table is introduced of the various causes to which the sounds have been ascribed; copied from Longet, and augmented by the author, whose own explanation, with which it closes, is the common one, with the exception that he does not allow the muscular action of the heart to enter into the composition of the first sound, on the ground that this would involve a want of synchronism in the fibrillar contraction.

Passing, in the second chapter, to the phenomena of the heart's action in relation to its modification by disease, Dr. Hayden considers the causes and mechanism of displacements of the heart, and discusses the theory of their mechanism suggested by Dr. Douglas Powell, that the displacement is the result of traction by the unaffected lung. He rejects this explanation both on theoretical considerations and on the ground of an experiment of his own, in which the sudden collapse of an over-distended lung had no effect in moving the mediastinum beyond its normal position. Reduplication of the first sound is explained by Dr. Hayden as the resolution of the sound into its constituent elements, the impact of the heart against the chest-wall, and the tension of the auriculo-ventricular valves. He founds this explanation on the character of the portions of the reduplicated sound, and the explanation ignores the very obvious analogy with the reduplication of the second sound. The clear dependence of the latter on a synchronism of the two sides of the heart renders Dr. Hayden's different explanation of the reduplication of the first sound at least improbable. The account of the mode of action of the heart is drawn largely from Dr. Sibson's work, and is followed by a description of the phenomena attending the pulse.

In the chapter on physical signs of disease of the heart, the various murmurs indicative of valvular disease, or due to other causes, are considered at length.

In his account of dynamic murmurs Dr. Hayden discusses incidentally the relationship of heart murmurs and of chorea. His experience gives great weight to the opinion which he expresses, and which, of special interest in connexion with the late discussion on the subject, is at decided variance with that of many modern authorities. He denies all rheumatic relationship of chorea, and does not believe that it is ever due to valvular lesion of the heart, rheumatic or non-rheumatic. The frequency with which vegetations are found post mortem in cases of chorea he considers has not the significance often attached to it, and, on the other hand, shuts off from the advocates of the embolic theory their negative refuge, "that absence of murmur is no proof of the absence of even serious organic disease of the valves of the heart." Further, he turns upon them their own weapons, and asserts that whilst a (permanent?) murmur may be due to other causes than structural alteration of the valves, "the latter, in a degree capable of deranging health and appreciable to the eye of the anatomist, must and actually does always give rise to murmur so long as the heart acts with ordinary vigour."

Twenty-five pages are devoted here, and as many further on, to the history of the presystolic murmur, of the significance of which Dr. Hayden was a very early advocate. Every article which has been published on the subject is analysed in more or less detail. Murmurs occurring between the sounds and not connected with either—"intersonal" murmurs, as he terms them,—Dr. Hayden considers we must reckon as a numerous class, and gives examples of post-systolic, pre-diastolic, and post-diastolic varieties. The two latter varieties appear to have been associated in Dr. Hayden's cases with partial incompetence of the aortic valve, and are new rather in name than in fact.

The short chapter on the causes of heart disease is less exhaustive in its style than the rest of the book; it consists of brief extracts and tables from various writers strung together with a few unimportant remarks. The treatment of this subject is indeed disappointing. When we turn, for instance, to learn what most modern opinions teach on the influence of syphilis as a cause of heart disease—a subject of great interest, of which something is known, and much more is, with reason, suspected,—we find it dismissed with the inadequate remark that "Ricord describes morbid changes of the heart and other organs which he compares to syphilitic tumours or nodes." A few facts about nodular syphilitic growths in the heart are given further on.

The long account of pericarditis is chiefly remarkable for an interesting collection of cases of pericardial adhesion, compared as to the effect upon the walls of the heart. The cases are drawn from the records of the Pathological Societies of London and Dublin, and Dr. Hayden's own note-book. He finds, from a comparison of the fifty-four cases, that only seven can be adduced in support of the doctrine that simple adhesion of the pericardium is competent to give rise to hypertrophy of the heart; and even these are not reported in such a manner as to inspire confidence, since in several the urine was not tested, nor was the disease of the kidneys excluded by examination after death. He therefore believes that, when hypertrophy of the heart is met with in cases of adherent pericardium, the connexion is, in the majority of cases, purely accidental. Dr. Hayden's treatment in acute pericarditis is invariably to administer mercury in small and frequently-repeated doses, half a grain of calomel every hour, pushed to slight salivation, subsequently iodide of potassium and counter-irritation; and for the removal of fluid, diuretics and purgatives, not blisters. Some cases of pericarditis are appended.

The section on diseases of the walls of the heart is chiefly remarkable for the exhaustive account, historical and clinical, of the conditions of hypertrophy, dilatation, and fatty degeneration. In the description of the first of these there is little that is new. Aneurism of the aorta is removed from its list of causes on the ground of some original observations which show, in Dr. Hayden's opinion, that aneurism of any part of the aorta is more frequently associated with a normal ventricle than with either hypertrophy or dilatation, and that the association of hypertrophy with aneurism, frequently observed, is accidental. The causes and symptoms of fatty degeneration are examined by the help of some extensive and valuable tables compiled chiefly from the Pathological Society's records. From these he believes that it is a disease of middle rather than of advanced life (although the figures point to the latter), and that men are affected twice as frequently as women. The "Cheyne-Stokes breathing," the peculiar rhythmical irregularity of respiration which has attracted so much attention, is discussed at length, and Dr. Hayden offers for it this explanation. The only lesion of structure commonly found in the cases being atheromatous and calcareous change, with dilatation in the arch of the aorta, he suggests that in sleep and repose, when the heart's action is most tranquil, the systemic capillary circulation fails from want of the contributory aid rendered in health by the elastic reaction of the aorta. Hence arise a suspension of tissue respiration and accelerated breathing, and as the systemic capillary circulation becomes established, the *besoin de respirer* is less urgent, and respiration gradually subsides till a period of apnœa arrives, to which the exhaustion of the patient contributes.

An extensive table presents the circumstances, symptoms, physical signs, mode of death, state of the aorta, state of the valves of the cavities and walls of the heart, of the fibres, and of other organs in eighty-eight cases of fatty heart. It is intended to be supplementary to the tables published by Dr. Quain in 1850.

Other forms of degeneration of the heart and growths in its tissue are subsequently described, and then the symptoms and signs of endocarditis. It is interesting to find that Dr. Hayden confirms the opinion of many careful observers that the murmur of endocarditis never commences suddenly; that its gradual development can always be detected in an alteration of the sound before a distinct murmur is perceptible. In the treatment of endocarditis Dr. Hayden adopts the same vigorous measures which he employs in pericarditis, leeching, and mercury to salivation, being his usual measures.

Diseases of the several orifices of the heart are described at great length, with the addition of numerous illustrative cases, and a very interesting table is given of eighty-one cases of mitral stenosis. This and other chapters are illustrated by numerous sphygmographic tracings. Neuroses of the heart are described at length, and among them angina pectoris and exophthalmic goitre receive their due attention. Both in this chapter and in the last, on diseases of the aorta, Dr. Hayden gives us the same wide review of contemporary and historical facts and opinions, as well as numerous cases.

The work is certainly not one for students, but as a conspectus of the scientific literature of diseases of the heart and aorta, and as a record of original experience and opinion, it deserves an honourable place in medical literature.

DRS. T. LEWIS AND D. D. CUNNINGHAM ON THE SOIL IN ITS RELATION TO DISEASE.

THE Appendix to the last Annual Report of the Sanitary Commissioner (Dr. J. M. Cuningham) with the Government of India, contains an excellent paper "On the Soil in its Relation to Disease," by Drs. Lewis and D. D. Cunningham. Since Professor Pettenkofer directed attention to the composition of the air in the soil, and proposed the carbonic acid in it as a measure of its impurity, various researches have been made, the general result of which is not on the whole favourable to Pettenkofer's proposal. The permeability of the soil—i.e., the freedom with which atmospheric air enters it, as well as the composition of the soil itself, so affects the amount of carbonic acid in the air in the interstices, as to render it probable that the carbonic acid cannot be taken as a measure of ground impurity. But this, while it throws a difficulty in the way of forming an opinion as to the amount of impurity in soil-air, does not at all lessen the belief that a knowledge of the composition of soil-air is of great hygienic importance.

The report of Drs. Lewis and Cunningham is the best we have yet seen on this topic, and it is a most creditable piece of work. It examines into all the conditions during an entire year; the amount of carbonic acid in the soil-air in two localities at 3 ft. and 6 ft. in depth in each case; the temperature of the ground at those depths; the temperature of the atmosphere; the velocity of the wind; the rainfall and the height of the ground-water are given; and a series of graphic representations place the results before the eye of the reader very clearly.

In Calcutta the lower stratum of ground-air is richer in carbonic acid than the higher stratum. The maximum monthly amount in the first locality occurred in September, when it reached 12 volumes per 1000 of air; the minimum was from March to July, when it was nearly 8 volumes per 1000. In the 3-foot stratum the air was at its maximum also in September, when the monthly average was 11 per 1000, and at its minimum in May, when it was only 4 per 1000. The carbonic acid was, therefore, less in quantity 3 feet from the surface than at 6 feet, and suffered greater fluctuations, but the period of maximum and minimum coincided in the two depths. The authors compare these results with the Munich rates, but we will not enter into this. In the second locality the observations were only carried on for six months, and the remarkable fact appears, that while the fluctuations in the amounts of carbonic acid in the two localities fairly corresponded, the amount of carbonic acid was considerably less in the second locality than in the first. These localities were only 50 yards apart, and to all appearances the nature of the soil was the same; and yet, while in locality No. 1, at 6 ft. from the surface, the maximum carbonic acid was 12 and the minimum 7 per 1000 volumes, in locality No. 2 at the same period the numbers were 7 and 5. The authors remark that "the processes going on in the soil must have differed materially in degree if not in kind, and if such processes have any influence on health, it is obvious that people inhabiting one end of the building must have been exposed to different hygienic conditions from those living at the other end." This is possible, but to us the inference would rather be that carbonic acid is really no measure of the processes going on in the soil, and that some other measure must be devised.

On comparing the amount of carbonic acid in the soil-air with the temperature of the soil, the authors found that the lines of temperature neither directly nor conversely corresponded with those of the carbonic acid. At the same time, one point came out—viz., that the periods of greatest difference in the amounts of carbonic acid in the 3 ft. and 6 ft. strata coincided with the greatest difference in temperature between these strata. Perhaps this was a mere coincidence; at any rate, it was the only indication of any relation of carbonic acid to soil temperature. The soil temperature was at its lowest in January, when the weekly mean at 3 ft. reached 68°, and at 6 ft. 72°, and at its highest in July and August, when the temperatures were 83° and 82°.

The atmospheric temperature in no way influenced the carbonic acid in the soil-air. The rainfall had a distinct influence on the carbonic acid, the main periods of elevation of which occurred with the rainfall, and the period of depression occurred with drought. There was also a general coincidence with the water-level. The velocity of the wind did not apparently affect the carbonic acid, except that in April and May, when the movement of the wind was great, the carbonic acid in the 3 ft. stratum of one of the localities which was exposed suddenly sank, while in the other more sheltered locality no such sinking occurred. The authors think this discrepancy may have been due to the wind.

The outcome of the whole inquiry as to the carbonic acid in soil-air is thus, we think, to show that no great results arise from it; at the same time, we trust that this investigation may still be carried on in Calcutta, and the question definitely settled.

Another very interesting point referred to by the authors is the relation of the total Calcutta mortality and the prevalence of fevers, dysentery, and cholera to the soil. Nothing obvious was made out, except with regard to cholera. The authors give a graphic plate, showing the weekly cholera mortality in Calcutta in connexion with the water-level, rainfall, and temperature of air and soil. They remark that the "only remarkable coincidence appears to lie in the converse relation which water-level, and in a less marked degree rainfall, bear to the prevalence of the disease;" when the latter is "at a maximum the water-level is at a minimum, and when the water-level is at a maximum the prevalence of cholera is at a minimum." On looking at the table, however, we think this expression is rather too strong, and the point is of so much importance that we will give the figures for the whole year.

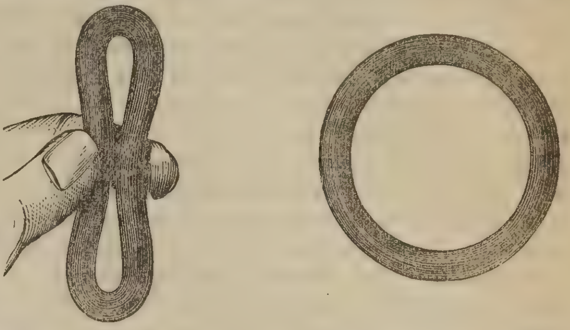
We have given this table in full not only because it is the most complete yet published, but because there is sure to be difference of interpretation. From July to Sept. 13th the water rose in the soil until it was five feet nearer the surface. The deaths from cholera, never very many, fell in August, and, at the time of highest water, had fallen to 21 in the preceding month. But from Sept. 13th the water fell with great regularity to the end of the year, and yet the cholera deaths remained practically the same. In the four weeks of September there were 24 deaths; in the four weeks of December, 29. Not until January 17th does a decided rise occur in the cholera deaths, and then the water was 14¾ feet from the surface. The deaths remained at nearly the same number until May 2nd, when they reached the maximum of 94. But between January 17th and May 2nd the water sank only five inches, and that was at a depth of 15 feet from the surface; while in the previous four months it had sunk 4 feet—namely, from 10 to 14 feet—without any more marked influence on the cholera deaths, although the drying ground was much nearer the surface. To this it may be said that the influence of the drying soil required time to act, and that we must look at the whole coincidence instead of trying to dissect it. But if this be so, how can we account for the last part of the table? The water-level remained from May 2nd always at its lowest point—viz., 15 ft. 2 in.—from the surface until June 27th, and yet during the whole of this time the cholera deaths were rapidly falling from 93 to 18 per week. If, then, the drying soil required time to act, what stopped its continued action after May 2nd? Why did it not increase the cholera after May 2nd? The temperature of the ground was then rising; the water-level was as low as it could be, and yet cholera declined. The coincidence, not it appears to us strong anywhere, fails here completely. At the same time it would be rash to say that the question is at all clear. In Calcutta the rule as to cholera is that it begins to increase in February, and is most fatal in March, April, and May. April appears, from Macpherson's tables, to be the worst month (19,328 deaths in twenty-six years), and August the best month (3440 deaths in twenty-six years). Now, in April, the water-level is lowest (15 ft. from surface), and in August is rising to its maximum of 10 ft. from the surface, which it reaches in the middle of September. Here, then, it may be thought is a coincidence too striking to be put aside. It may be so, but, as already pointed out, the table before us shows, it seems to us, points which are not to be reconciled with this view. At any rate, we trust the observations will be continued, and the matter as regards Calcutta set at rest.

New Inventions.

NEW FORM OF PESSARY.

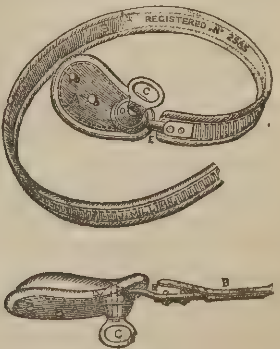
The pessary of which an engraving is given possesses manifest advantages. It consists of a watch-spring coiled spirally, with the extremities left free; this is encased in caoutchouc, and in its external appearance resembles many of the various ring pessaries at present known. The advantages of this pessary will appear by reference to the engraving on the left, where it is shown collapsed for facilitating its introduction; when *in situ* it expands to the circular form, as shown on the right of the figure, or assumes such other shape as may best accommodate its contact with surrounding parts. The pessary is made in sets of three, and has the additional merit of being inexpensive. A detailed explanation of these pessaries appeared in a recent number of *Le Progrès Médical.* It is manufactured by Messrs. Salt and Son, Birmingham.



IMPROVED TRUSS.

Medical men are often troubled by patients with regard to their trusses, which they cannot fit so as to keep up the hernia. Upon examination it is frequently found that the pad simply requires to be turned a little to the right or left, or a little upwards or downwards, or inwards, as the case may be. The pad soon works back into its old position, and the hernia passes as before, so that the truss has to be sent back to the instrument-maker with instructions to alter the direction of the pad.

Mr. Millikin, of 35, St. Thomas's-street, Borough, S.E., has put before us a truss which seems to overcome many disadvantages. It will be seen from the diagram that the truss consists of the old German pad and spring, between which is placed a ball-and-socket joint, which can be fixed in any direction whatever, and also allows of great or little pressure, to be exercised at will. The fixing handle, c, folds down upon the truss, so that it does not show through the dress. The pad may be placed in any position. The extra weight and thickness are inconsiderable. The instrument is well made and is not expensive.



THE LANCET.

LONDON: SATURDAY, DECEMBER 4, 1875.

If we have seemed to oppose, with unusual pertinacity, Mr. Marshall's proposal to institute a compulsory examination in Anatomy at the Royal College of Surgeons at the end of the first winter session, it is not because we are ignorant of the existence of some of the evils which that scheme is intended to remedy, but because we feel that it will not only not remedy them, but will call into activity others that are at present practically dormant and of no effect. Mr. Marshall has recognised the existence of the disease, but has failed to detect its cause, and has therefore erred in the measures he proposes for its treatment. We fully admit the large number of the rejections at the primary examinations, and are not unwilling to believe that the knowledge of anatomy acquired by many of the candidates is both scanty and imperfect; nor can we gainsay the statement that much valuable time is wasted in the first year of the student's curriculum. But while Mr. Marshall would account for these things by the mental incapacity of the average student, the want of training and of intellectual discipline of those who *now* enter the medical profession, and the inherent idleness and moral depravity of medical students, we prefer to acknowledge other causes—namely, the scanty and irregular supply of subjects for the purposes of dissection furnished to the medical schools by the Inspector of Anatomy, and the false and defective method of testing the candidate's knowledge adopted by the Board of Examiners and sanctioned by the Council of the College. If this explanation be correct, it is manifest that the College has in its own hands a simple remedy that is both effectual and satisfactory, without hatching a scheme that, if rigorously carried out, would inflict great hardship and injustice on the student, whilst it left the *fons et origo mali* untouched.

In another column we publish a return of the subjects supplied by the Inspector of Anatomy to the Metropolitan Medical Schools since the commencement of October. A glance at that return will suffice to show that there are at the present moment many students, both first and second year, who must perforce remain idle for want of the opportunity to dissect. As we showed last week, for every hundred first-year's students at least fifty subjects will be required in the course of the winter session to furnish an upper and a lower limb to each student. In addition to this, each student ought to dissect all the parts of the body in the course of the twelve or eighteen months that intervene between the end of the first winter session and the first professional examination; and at least fifty subjects will be required for every hundred second- and third-year students, in addition to the parts of the subjects supplied for the first year's men that are available for senior students. But besides these, five or six subjects will be required by the teachers and lecturers at each school for the purposes of demonstration and instruction. In the course of one year, therefore, where there is an anatomical class of two hundred students, half of whom are first-year and the other half second- and third-year, about one hundred subjects will be necessary to ensure adequate study and instruction; whereas the supply in some instances is not much more than half of this. It may be objected that this estimate is too high, and that if a student dissect the limbs during his first year he need not dissect them again in his second or third year. We maintain, however, that this estimate does not exceed the actual requirements, and that to allow the necessarily imperfect dissection of the limbs in the first year to exempt the student from dissecting these parts again in his second or third year would be a short-sighted policy. An intimate acquaintance with the anatomy of the muscles, vessels, nerves, bones, and ligaments of the limbs is of the highest importance to the surgeon. The reduction of fractures and dislocations is greatly facilitated, indeed sometimes only possible, by the aid of an accurate knowledge of the shape of the bones, the nature of the articulations, the position of the ligaments, and the situation and action of the muscles that move the limb or protect the joints. The arrest of hæmorrhage and the safety of life or limb are often entirely dependent on the surgeon's knowledge of the position and relations of the bloodvessels that pass from the trunk and are distributed in the limbs; and the records of surgery prove that, unless the surgeon be thoroughly acquainted with the anatomy of the extremities, irremediable errors in diagnosis and serious misapplications of treatment may at any time occur. Compared with the extremities, the other portions of the body are of minor importance to the majority of practitioners, so that, even if the student were to satisfy the requirements of the elementary examination on the anatomy of the limbs at the end of the first winter session, he should still be compelled to dissect them again before the ordinary Primary Examination. To enable him to do so, a supply of subjects equal to that we have named would be desirable. If the College of Surgeons wishes to attack the evil at the fountain-head, it should use its influence to secure the adoption of some measure by which an adequate supply of subjects would be ensured to the medical schools, even if it be necessary to put a little pressure on the venerable Inspector of Anatomy, whose post seems of late to have lapsed into a sinecure. What is especially wanted is a good supply of subjects at the early part of the session, to enable students to commence dissections without delay. The alteration made in the Anatomy Act in 1871 empowered the lecturers on anatomy to collect and preserve subjects during the four months prior to the beginning of the winter session, but owing to the difficulty of procuring the bodies it is almost impossible to reap the full benefit of that regulation. There are complaints from several teachers, who were prepared to receive any number of subjects during the vacation, that they were unable to procure anything like enough for their purpose. The result of this deficiency is, as we pointed out last week, that two or three months of the session pass away at the large schools before any of the first-year students can obtain parts for dissection, and it is not until after Christmas that every student has been able to get a part. Whereas, if there was a proper supply of subjects early in the session, each student would be able to begin dissection as soon as he had learnt osteology, and, having no temptation or excuse to be idle, "would," to use the words of Mr. Marshall, "feel at once that he must work without delay; he would understand for what and how, within defined limits, he is to devote his time and energy, cultivate his powers of observation, arrangement, and memory, and use his opportunities of anatomical study." And to have work on which students could at once begin "would probably be the means of diverting some students every year from an idle and profitless course of life; and it would save others, now injured, perhaps ruined, from want of a defined purpose, from irresolution, inexperience, and defective foresight."

We venture to believe that, if the suggestions we have thrown out were acted upon, a healthy stimulus would be given to the industry and ambition of students and to the efforts of teachers, and that, as soon as the College had adapted its mode of examination to the requirements of modern times, the evils which are now so deeply deplored would be reduced to a minimum, if not entirely eradicated.

That a causal connexion exists between constitutional syphilis and aneurism has long been a matter of faith with many, which has now and then found expression, but seldom in a more striking and, at first sight, even convincing manner than in the paper read before the Royal Medical and Chirurgical Society at its last meeting, by Mr. Francis J. Welch. Enjoying unusual opportunities for the study of diseases of the vascular system and of syphilitic lesions, he has arrived at the conclusion that the unusual prevalence of aneurism of the aorta among soldiers is in great measure owing to the prevalence of syphilis in the ranks. He has found that as many as 50 per cent. of the cases of aneurism he met with, and 46·1 per cent. of examples of aortic disease, were the subjects of well-marked syphilis, the lesion being an endarteritis, leading to dilatation of the vessel and to new growth in the walls of the aneurism. In round numbers, he places 66 per cent. of the cases of aneurism, all presenting this particular endarteritic change, to the account of syphilis, the remainder being chiefly divided between alcoholism and rheumatism. With this broad and clear proposition before them—viz., that syphilis is a direct cause of aneurism by its leading to a distinct change in the inner coat of the aorta,—it cannot be wondered at that several objections were raised to its acceptance by the speakers in the debate which ensued upon the reading of the paper—objections which were fairly faced by Mr. Welch, who candidly admitted that he was astonished at the results he had obtained. The question raised in the course of the debate as to the precise significance attached to the word "syphilis" in the Army Returns need not be followed here.

The pathological side of the question is, however, one which may fairly well be reviewed, because it is here, if anywhere, that we may expect to find points of agreement between the civil and military records. And, firstly, it cannot be denied that syphilis does play a certain part in the etiology of aneurism, but withal a subordinate one, and certainly not to such an extent as Mr. Welch would have us to believe. That syphilis does lead to fibroid disease and degeneration of the bloodvessels is an admitted fact; but that it is only one factor, and by no means an important one, is, we think, shown by reference to recorded cases of aneurism. One argument, not without weight, is that adduced, we believe, by Mr. Myers in his paper "On the Prevalence of Aortic Aneurism in the Army" (Pathological Transactions, vol. xx.); to the effect that if syphilis be a potent cause in the production of aneurism, how are we to account for the striking disproportion between the prevalence of the latter affection among the male and female portions of the community? In one of the metropolitan hospitals for the seven years ending 1873 (we quote from the Registrars' Reports), we find that, out of 39 cases of aneurism of the aorta under treatment, there were but 5 females; whereas in the same institution during the same time there were of constitutional syphilis as many as 221 males and 283 females treated in the medical and surgical wards. Or if we refer to the volumes of the Transactions of the Pathological Society, we find that of specimens of aortic aneurism shown at that Society since its foundation no fewer than 105 occurred in male subjects, and 17 in female subjects. Yet of this large number of cases, in 110 there is no mention at all made of syphilis in the previous history of the patient, its presence being signified in only 7 cases, and its absence noted in but 5. We would by no means desire, however, to lay too much stress upon statistics such as these; for it is but fair to mention that it is only in the later years that we find any reference, positive or negative, made to syphilis in these cases at all. At the same time, were any of these subjects "saturated with syphilis," that fact could not have escaped notice, and would have been recorded. In one case, indeed—that of a specimen of "nummular aortitis," shown by Dr. Goodhart last year,—there were evidences of syphilis obtained after death, although no history of the disease was extracted from the patient. In these records, too, the fact of intemperance is noted frequently, and of rheumatism occasionally, where syphilis finds no place.

There remains, however, another aspect of this question—viz., how far must we accept the view propounded by Mr. Welch that the endarteritic changes he describes are syphilitic? A similar opinion has been long held by Dr. Aitken, who, however, so far as we understand him, would have us to believe that there is a specific feature stamped upon the lesion by which it can be recognised. Mr. Welch, however, admits that this nodular endarteritis terminating in atheroma is met with in states other than syphilitic. Now of this we are certain: that there is a special form of arterial disease—not an endarteritis, but an affection rather of the outer coats of the vessel—which is undoubtedly syphilitic. It is met with perhaps most frequently in the cerebral arteries, and is a not unusual cause of thrombosis. But endarteritic changes are met with daily in post-mortem examinations in at least one-half of the cases examined. Following the author of the paper on this point, we should get one-fourth of the cases examined in the deadhouse to be subjects of syphilis; and as these cases may be supposed to be representative of the whole community, we may fairly infer that in that proportion does syphilis exist amongst us! Such a result would not be, to say the least, encouraging in the civil community, in whatever light it may be regarded in the army. Then the intimate pathology of the change in question bears on it nothing distinctive of syphilis. To be sure, this is not saying much, at any rate in the present state of pathological science, which apparently sees nothing in syphilitic lesions distinctive from "chronic inflammation"—whatever that vague and unsatisfactory phrase may mean. But this, at any rate, we do know—that changes such as these are produced by undue strain upon the vessels; and we cannot help thinking, with Mr. Myers, that to this cause is due the great prevalence of aneurism among soldiers. Aneurism is proportionately almost as prevalent among hammermen and smiths, and we do not invoke syphilis to its etiology in these classes. The contention, indeed, lies within a narrow compass—viz., whether syphilis is a direct or a predisposing cause. Mr. Welch thinks the former; his opponents the latter, and regard undue vascular tension to be the chief factor in the production of aortic disease and of aneurism. The comparative infrequency of syphilitic disease of the heart among soldiers, as pointed out by Dr. Powell, is certainly significant.

Although, then, we may differ from Mr. Welch, we accord him all praise for having raised this question and placed it before us in so striking a light. It will serve the very useful purpose of directing attention to the subject, and will lead doubtless to the publication of facts bearing upon it culled from other branches of the community than the public services. To all those who intend to take up the subject we would venture to give one word of warning—viz., to be particularly careful as to the data upon which the question of the existence or non-existence of syphilis is based. There are notoriously few subjects more difficult to elucidate from the history of the patient himself than that of syphilis, and much of the material accumulated on this head must be regarded with suspicion, unless there be recorded clear and distinct evidence of the syphilitic taint. In such an investigation, too, the subject must be viewed from all sides; and, having obtained a history of syphilis, any other possible cause of vascular derangement and deterioration must be sought for, and its absence proved, before it will be possible to state positively that the disease in question is at the root of the arterial lesion. As the case stands at present, most of us would agree with the cautious and thoughtful words of Dr. Parkes—"There is no reason to think that syphilis prevails more among soldiers than among the civil male population of the same class. It is therefore unlikely that an excess of syphilis, if it really occurs among soldiers, and if it actually predisposes to aneurism, as seems probable, could produce eleven times as many aneurisms as in civil persons."

* * *

The great trial for murder which has engrossed public attention for so many weeks past was brought to a conclusion on Wednesday. The verdict of "Guilty" against Henry Wainwright was the only one which it was possible for the jury to return, so complete in all respects was the chain of circumstantial evidence against the prisoner; but the complicity of Thomas Wainwright, even as an accessory after the fact, was a matter which was far less clearly demonstrated by the prosecution. Much of the evidence, and the most important evidence, bore upon facts having a medical interest; and seldom has the science of medical jurisprudence been laid under heavier contribution than in the present instance.

The first point to be determined was as to whether the deceased was the victim of suicide or murder. The counsel for the defence dwelt with some emphasis on the possibility of the unhappy woman having committed suicide; but a calm consideration of the facts renders such a view, in our opinion, absolutely untenable. Two bullets were found within the skull, one in the cerebellum, and another lying over the body of the sphenoid bone. The line of the former was marked by very considerable extravasation, so that it was probably the first fired, and certainly entered the skull during life. A third bullet had been fired, apparently from behind, and had lodged in the hair-pad worn by the deceased. Of these bullets it may be said that the wounds caused by two of them were sufficient to produce almost instantaneous death, while the concussion of the third which lodged in the pad was probably sufficient to produce insensibility. Apart from other facts, it would be in the highest degree improbable that the bullet found in the pad had been fired by the deceased herself. In addition to the bullet wounds, a deep gash dividing the trachea and big vessels, and having the appearance of having been cut *from right to left*, was found in the throat. Although this wound had divided the big vessels, it had bled only slightly, so that its infliction was certainly at a time subsequent to the injuries inflicted by the bullets. The counsel for the defence urged that it might be possible for a person with two bullets in the brain to inflict a suicidal wound in the throat, and he stated that he had read of cases in "Taylor" which gave credence to such a belief. It is true that in the work referred to several cases are recorded in which consciousness was retained after very severe injuries to the head, but such cases are mentioned as exceptional, and in the case under consideration the almost entire absence of hæmorrhage from the throat wound, and the strong probability that one bullet was fired directly from behind, seem to render the theory of suicide absolutely untenable.

The next point was, how long had the deceased been dead? To this the medical witnesses very properly gave a most guarded reply, that, judging from the amount of mummification and adipocerous change, at least a year had elapsed. On this point both Mr. Bond and Mr. Larkin were asked in cross-examination "whether it was not a fact that the process of decomposition was divisible into two well-marked stages, one characterised by evolution of inflammable gases, and the other characterised by mummification?" We confess we have been unable to discover the import of this question, and we desire merely to place it on record as a forensic curiosity. It is at least a presumed fact that the evolution of gas can be hardly recognised in bodies buried immediately in the earth.

The great medical interest of the trial centred in the identification of the remains, which were too far decomposed to allow of any superficial recognition. The presence of the female organs of generation placed the sex beyond a doubt, and it was rendered highly probable from the discovery of a wedding ring and "keeper" in the grave that the deceased had at least stood *in loco uxoris*; but, from an examination of the uterus, Mr. BOND and Dr. MEADOWS (although they both agreed as to the impossibility of speaking with certainty on the point) had come to different opinions, the former speaking in favour of, and the latter being opposed to the view of previous pregnancy.

That the colour of the hair of the deceased coincided with that of HARRIET LANE was not disputed, and consequently the question of the effect of chloride of lime on the hair was not raised, albeit that it seemed one out of which counsel might have made some capital.

The age of the deceased was a point of great importance, and we cannot admit that it was established with as much certainty as it might have been. The witnesses relied entirely upon the evidence afforded by the wisdom teeth, three of which were fully and one partially cut. From this it was inferred that the age of the deceased was about twenty-five. Surely, however, this was a somewhat hasty conclusion from such data. The period of the eruption of the wisdom teeth is generally stated to be between seventeen and twenty-five, and it is not unfrequently delayed even later. The condition of the teeth of the deceased would show that she was certainly over seventeen, but we cannot see that any other conclusion could be drawn from this fact. It was to be regretted that no examination was made of the epiphyses of the bones, from which, we think, much valuable information might have been derived.

Mr. AUBIN's evidence about the sutures of the skull was wholly inexplicable, and it was said that his confusion was so great under cross-examination, that the counsel by whom he was called found it difficult to account to the jury for his answers on those subjects to which he had come to speak as an expert.

With regard to the scars, that on the right leg was fully established, while that alleged to exist on the left leg remained in the condition of a mere allegation. It is certainly surprising that neither side made any attempt to demonstrate the presence or absence of lineæ albicantes upon the abdomen.

The height may be considered to have been fully established, and the trifling discrepancy of three-eighths of an inch, if not due to faulty apposition of the limbs, may be considered as accounted for by the theory put forward by Mr. BOND as to the shrinking of the intervertebral cartilages.

The case will long be remembered as one which presented points of unusual difficulty to the medical jurist, and it was undoubtedly due to the great care shown by Mr. BOND and Mr. LARKIN in carrying out the necessary investigations and examinations that the satisfactory bringing home of the charge to the prisoner was due, and we are glad to observe that the services rendered by these gentlemen received a handsome recognition from the Lord Chief Justice.

◆

THE proceedings of the meeting of the Medical Defence Association held this week present features of considerable interest to a large number of our readers. Apart from the general and very difficult question of the way in which unqualified medical practice should be dealt with, the special experience of this Society, or rather of the Eastern Branch of it, as a prosecuting Society, is both interesting and instructive. Under the guidance of their able legal advisers, Messrs. GREEN and PRIDHAM, of Bedford-row, this branch has instituted no less than three successful prosecutions against unqualified practitioners who abound at the East-end of London, and who are too often protected in some way by members of the profession. The curious thing about these prosecutions is, that they have been carried out, not under the Medical Act, but under the Apothecaries Act. It is very remarkable, after the medical legislation of 1858, that we should be reverting to that of 1815. But the fact is easily explained. The use of the Medical Act, as far as the punishment of unqualified practice is concerned, is very limited. It only contemplates the prevention of the false use of titles. To a considerable extent it has succeeded in this. But a quack, while avoiding the false use of any recognised titles, may easily give his house or shop a name which has the effect of conveying the impression to the public that he is a medical practitioner. But the Apothecaries Act is available for punishing a man for practising. It would, after all, be very monstrous if there were no such law. The Legislature in its wisdom has recently made it penal for men to sell poisonous drugs without being licensed to do so by a Society constituted for the purpose of examining men in their knowledge of such things. With what consistency could it abstain from forbidding ignorant men, under the guise of medical practitioners, from dispensing potent drugs? This would be to permit a greater evil while prohibiting a lesser one. And the profession is not a little indebted to the Eastern Branch of the Medical Defence Association for reviving the use of this comparatively forgotten Act.

As regards the general question, we entirely agree with the President, Dr. RICHARDSON, and other speakers at the meeting that, if the Association is to succeed and to command attention and respect, it will have to look at unqualified practice rather from a public standpoint than from a professional one. It augurs well that this view of the matter was general and found clear expression in one of the amendments. It cannot be too frequently or plainly stated that the public suffers more than the profession by unqualified practice; that deaths happen which should not happen; and that worthless information as to the cause of death is taken in great quantity from unqualified practitioners by the registrars of the country, and with the consent of the Registrar-General, thus vitiating the public records of mortality. As Dr. ROGERS said, if the public get the idea that the sole object of the members of the Association is to protect the medical profession, the Association will fail. It is to be hoped that ere long we shall have a public prosecutor who will initiate and carry through prosecutions against breaches of the Medical Acts. Pending this the medical corporations ought to do the work. But, failing them—and they are very indifferent,—we do not see how the work is to be begun unless it be undertaken by some such Association as that under discussion. We see that such action on the part of a Medical Association—still more of a medical man—is invidious and liable to misconstruction. But we must hope for such a display of wisdom and prudence in these prosecutions as will prevent such misconstruction. And we would urge upon the Association to use its influence to procure the appointment of a public prosecutor who should relieve it of prosecuting functions.

Annotations.

"Ne quid nimis."

"THE LANCET" COMMISSION ON LUNATIC ASYLUMS.

NOTHING marks the recent progress of medical science more clearly than the increased attention bestowed on mental disease. Not many months ago it was the reproach of our educational system that the merest tyro, armed with a diploma in surgery, might sign away the liberty and lifelong fame of a fellow subject, although his qualification for the possession of this power did not guarantee his having read a page of any work on mental disease, heard a single lecture on the subject, or seen a case. Something has been done to amend this deplorable state of matters, by at least one licensing body. This glimmer of light perhaps only makes the general darkness more apparent, but it may be welcomed as a portent of better days. Before, however, the study and treatment of disease of the mind can be placed on a footing of equality with the study and treatment of disease of the body, much remains to be accomplished. The first step should be to collect the facts in regard to insanity, its conditions, cure, and mortality. Such data can only be obtained in the asylum. With a view to obtain and arrange the information required, we have instituted an inquiry at some of the principal institutions in and near London. The first of a series of Reports embodying the facts observed and collected will be found in this day's issue. The asylum selected for the introductory notice is the most recent in construction, and, on that account, will offer points of interest with which other asylums may be conveniently compared. By devoting some space to this first report, we shall be able to curtail the summary of features calling for description in the reports which follow. The deductions as to matters of moment, such as the distribution of cases in institutions, on the basis of a classification into "curable" and "chronic," and the success or failure of particular methods of treatment, will be deferred until all the reports are before the public, when comparisons may be fairly instituted. Such evils and abuses as may be discovered will be fearlessly exposed, but it is needless to say the inquiry has not been undertaken in any spirit of suspicion, and the aim is primarily scientific and professional. To the public an inquiry like that now in progress can scarcely fail to prove of vital interest. It will show how far the needs and comforts of the insane are cared for, the distressing symptoms of their mournful maladies alleviated, and their pains and griefs assuaged. The urgent necessity for such an investigation cannot, we think, be over-estimated or its practical value too highly appraised.

THE MARINE MEDICAL SERVICE.

IN accordance with a request from the medical inspector of emigrants for the port of London, we sent him last week the names of two emigrant ships stated by us (on excellent authority) to have sailed from that port with unregistered surgeons in medical charge. Mr. Humphreys informs us, in reply, that the surgeon on board the *St. Osyth* was registered in January, 1869, and that the *Blairgowrie* (the second vessel referred to) embarked her emigrants at Plymouth (clearing, however, from the port of London), so that the London emigration office was not responsible for the surgeon. We are glad to place Mr. Humphreys' communication on record at once, as it shows that the emigration medical officers are fully alive to the importance of carrying out the law in its integrity. But we may fairly paraphrase in effect the remarks of the *Pall Mall Gazette* on this subject, and ask what steps would or could be taken by any Government officer if he found an unregistered or unqualified surgeon on board? And, moreover, what machinery exists for discovering the qualifications of surgeons on board ships other than emigrant ships? It must be remembered that vessels carrying only cabin (i.e., first-class) passengers, do not come under the notice of the emigration officers at all, nor have these officers, of course, anything whatever to do with large telegraph and other steamships that are compelled by the 230th section of the Merchant Shipping Act, 1854, to carry a surgeon. It is, as we suppose, chiefly on this account that *The Times* comments on the subject; for, as may be seen in a Parliamentary paper just issued, it is quite possible for a large steamship to start for New York, or a sailing and first-class passenger ship to sail for Melbourne, with a medical officer in charge not only unregistered, but unqualified.

Certain lucubrations that have appeared in provincial journals indicate that some of the medical inspectors of emigration are very much "exercised" as to these official returns, and our remarks thereon. But the question is one that (taken, as it undoubtedly should be, in its widest aspects) is entirely beyond their control. Of the fifteen unqualified men quoted in the Parliamentary Returns referred to above, nearly all shipped on whalers, and of the rest, one only could possibly have come under the notice of the emigration medical officers.

These and other remarks as to ship surgeons are made very much in the interests of our own profession as well as of the public. It is our duty to try to raise the status of medical officers in the Merchant Service, as well as in the Royal Navy, to a proper footing. And that status, either as to pay or position, will never be properly attained so long as it can be shown to the public by Parliamentary documents that the law has been broken, and that persons have been sent to sea in medical charge of large ships who would not be allowed to hold an appointment under the Admiralty, the War or Home Offices, the Local Government Board, or, in fact, under any imperial or local department in the kingdom.

EARLY DIAGNOSIS OF SCARLET FEVER.

AT the present moment it is very important for medical men to be acute in the early detection of scarlet fever. Such acuteness is creditable from a scientific point of view, and it is valuable as giving timely information to friends which enables them to isolate the case early, and reduce to a minimum the number of things and persons brought into contact with the patient. For the purposes of this early diagnosis the throat symptoms are most important. The sore-throat of scarlet fever is very different from other forms of sore-throat, and it is one of the earliest available symptoms, being noticeable from the first day of the attack. The appearance is that of an erythematous redness, affecting the soft palate extensively, thus differing materially from the ordinary forms of tonsillitis, which affect the tonsils only in the first instance. As Trousseau says—whose description of scarlatina is worthy of serious study—"In scarlatina, from the first day of the attack, the veil of the palate has a red hue, analogous to, but deeper than, that of the skin." When this condition of the throat is met with during an epidemic of scarlatina, with a very hot skin and a very quick pulse, accompanied with or preceded by vomiting, with a tongue with thick creamy fur, red borders, and prominent papillæ, the shrewd practitioner will be prepared for a case of scarlet fever. Dr. J. Lewis Smith, of New York, in his excellent work on the Diseases of Children, tells us, in his account of scarlet fever, that vomiting occurs in most cases within the first twenty-four hours, and has considerable diagnostic value. In 90 out of 117 cases which he carefully examined, he found vomiting to occur within the first twelve or eighteen hours. Of course when the eruption appears in addition to the above symptoms, the case is clear enough; but the practitioner who has carefully watched the group of facts which we have described will be as likely to discover the eruption for himself as to have it pointed out to him by others or by the patient.

THE CONTAGIOUS DISEASES ACTS.

THE opponents of the Contagious Diseases Acts have shown that their spirits are reviving. Ours are going down, but for very different reasons from those which they would ascribe to us. The annual conference of the various associations comprising the Northern League for the repeal of the Acts was recently held at Sheffield, and followed by a series of public meetings. If we may judge from the report of one of the meetings at the Albert Hall, at which the Right Honourable Mr. Stansfeld and Mr. Mundella were the M.P.s present, a very large audience seems to have been attracted by the subject and the speakers. The hall was filled in every part, the platform, balcony, orchestra, and stalls being largely occupied by ladies—many of them young,—who, we are informed, appeared deeply interested in the proceedings. Among the speakers, a medical gentleman whose name has stood forth conspicuously as an opponent of the Acts, from a statistical standpoint especially, seems to have proved too much, for he declared that wherever the Acts had been in operation, disease had not diminished but increased. But what we desire to call attention to is the fact that he gave examples of the working of the Acts, and "contended with considerable plainness of detail" for the conclusions he was advocating. Mr. Stansfeld fought, as might be expected, for the position which he has taken up against the legislation of the late Government, of which he was a member, with all the fervour and impetuosity of a convert; and Mr. Mundella advanced a great many statements in regard to the proceedings of the Royal Commission on which he sat as a member for six months, about which we should like to ascertain the testimony and opinion of other members. The great difficulty with which anyone really desirous of learning the facts has to contend is that it is impossible to say what is merely unsupported assertion and what is not. One never knows where to meet the opponents of the Acts, for when driven from a position they either resume it in a short time or bring forward old arguments with new faces. But on one point we should hope there can be no difference of opinion—viz., the indelicacy, indeed the indecency, of discussing such topics before crowded and mixed audiences. The *Sheffield Daily Telegraph* mainly addresses itself, in an able and excellent leader, to this point. Our contemporary says that the audience heard one side only, and they heard much that was utterly unreportable in print. A subject which modest men approach with a certain shamefacedness, or recoil from with irrepressible aversion, is, it seems, fit to be taken up by modest ladies! We cordially concur with our contemporary in all that it says when mincing misses fresh from school, and pious matrons, are asked in a tone of cheerful innocence to occupy their minds with a medical question which cannot be judged of aright unless there is a full knowledge of details, and the details of which are inevitably and unutterably indecent. It refuses to discuss the other side in its pages, holding that a debate on such a matter would itself be a contagious disease of rather a startling character, and one calling urgently for moral deodorisers and disinfectants.

THE WALLS OF THE UTERUS AFTER PREGNANCY.

THE difficulty of determining, from the state of the uterus alone, whether or not a woman has borne a child, was illustrated this week by the medical evidence given before the Lord Chief Justice at the trial of the brothers Wainwright. The difficulty in this case arose, not from the fact that the uterus was in a state of decomposition, but because no marks are left in the uterus which has once been gravid whereby the previous existence of such a condition can be established. At the same time, there are appearances which, when present in the womb, militate against the supposition that the organ has been gravid, though they do not exclude the possibility of such a condition having existed. One of these is unusual thinness of the uterine walls. In the great majority of women who have borne children the walls of the uterus remain permanently thicker than they were in the virgin state of the organ, for involution rarely takes place in such a degree as to reduce the womb to its original size. Yet cases do now and then occur in which the process goes on beyond its normal limits, and the uterus becomes reduced to a size considerably smaller than that of the virgin womb; indeed, it may be reduced to such a size as to elude detection by the most careful vaginal examination.

Other marks which may be left on the uterus as the results of pregnancy and delivery, such as fissures of the cervix, thickening of the lips, changes in the shape of the external orifice, may also be produced by disease and its treatment, so that singly or together they are almost valueless for the determination of the existence of previous gravidity. Some of the witnesses stated that it was not possible to form a positive opinion whether the woman had borne children or not. This accurately expresses our present knowledge of this question, and any further expression of opinion, however elicited, could only lead to conflicting evidence, such as that witnessed at the recent trial.

SANITARY CONDITION OF NORTHFLEET.

THE parish of Northfleet, at the last census in 1871, contained a population of 6515 persons, the considerable increase in which upon the number returned in 1861 was referred in the Census Report to "the extension of cement factories." According to the Registrar-General's last quarterly return, of 56 deaths registered in the Northfleet registration sub-district during the three months ending September last, 13, or more than 23 per cent., were referred to the seven principal zymotic diseases, including 5 from whooping-cough, 3 from fever, 3 from diarrhœa, and 1 each from small-pox and measles. It appears that since the end of September small-pox has become fatally prevalent in Rural-vale, Barrack-field, and Samaritan-grove; and scarlet fever in Wood-street and Bow-street; the whole of these localities being situated within the parish of Northfleet. These facts afford strong evidence of unsatisfactory sanitary condition, and it may be useful to consider who constitute the sanitary authority which is responsible for the public health of this community. The parish of Northfleet forms part of the Union of North Aylesford, the Poor-law guardians of which were, by the Public Health Act of 1872, constituted the Rural Sanitary Authority of North Aylesford, and were invested with the full responsibility in health matters for the whole of the union, excepting Strood, which forms part of the urban district of Rochester and Strood. Following the example of so many other rural sanitary authorities, the guardians of North Aylesford appointed their two Poor-law medical officers as medical officers of health within their respective districts, with small additions to their previous salaries.

RESEARCHES ON THE MODE OF TERMINATION OF THE NERVES IN THE CONJUNCTIVA.

In a short paper devoted to this subject in the *Archives de Physiologie* M. Poncet observes that the branches which innervate the conjunctiva proceed from the infratrochlear, frontal, and lachrymal nerves, with a few branches from the ciliary ganglion. In 1859 Krause first published his researches on the terminal corpuscles of sensory nerves. His conclusions were accepted by Kölliker, Ludden, Rouget, Frey, and Ciaccio, but have been lately opposed by Waldeyer. Arnold was also unable to admit their accuracy. Krause found about eighty club-shaped terminal corpuscles in the interior of which the nerves ended. These corpuscles he named *End-Kolben*, or terminal bulbs. The terminal bulbs consist of an envelope of connective tissue, containing a semifluid granular material. One or two nerves, with doubly contoured outline, run to these, twine round them, and penetrate into their interior, where they give off one or two branches that appear as fine short pale fibrils, terminating by slight enlargements. M. Poncet criticises several points in M. Krause's description. In the first place, working with chloride of gold and osmic acid, which were not in use when Krause made his observations, he finds the nerves do not coil round the outside of the corpuscles before penetrating them; secondly, that all the sensory nerve-fibres do not terminate in such corpuscles as Krause supposed; thirdly, that the part of the conjunctiva in which they are most commonly found is the upper and outer segment. This part of the conjunctiva is endowed with exquisite sensibility.

THE ANSTIE MEMORIAL FUND.

The committee of this fund met on Tuesday night at the house of Dr. George Johnson, Savile-row, and unanimously adopted the report of the executive committee, which we published last week. The executive committee must be congratulated on the happy and successful issue of this business, pleasing alike to the family of Dr. Anstie and to the numerous subscribers to the fund. Speaking roughly, about £1500 of this fund has come from the profession, and about £1000 from the general public. It may be easily imagined that such a sum has not been collected without much work on the part of the executive committee, and especially of the honorary secretaries, Mr. Brudenell Carter and Dr. Wharton Hood. They have their reward in the response of four or five hundred persons in and out of the profession. The rare and mingled virtues of Anstie will be long commemorated by the lofty inscription for which we are indebted to Mr. Simon, and let us hope they will be reproduced and perpetuated in those children whom he loved so much and left so soon, and to whose education the money of the fund is to be mainly applied.

ARMY MEDICAL DEPARTMENT.

Notices of the next examination of candidates for commissions in the Medical Department of Her Majesty's Army have appeared in our columns. The examination will be held on the 14th of February, 1876, and forty appointments are announced to be open to competition. The many and, as they seem to us, just complaints of army medical officers have been so fully and repeatedly set forth in our pages that it is simply a waste of time and space to discuss them further. That there is a very great amount of discontent in all grades of the medical service is undeniable. We hear it on all sides, and we do not hear of any attempt being made to remedy it. Mr. Gathorne Hardy has been interviewed by deputations of various kinds, questioned by members of the House of Commons, and the state of the departments was made the subject of a motion in the lower House, which was only withdrawn by Dr. Lush on the War Minister's declaration that the grievances of medical officers were engaging his most earnest attention. He has been frank enough in his apologies for the delay, but up to the present moment he has made no sign, and it is to be presumed that an expression of his intentions will only be yielded to Parliamentary pressure and the growing decadence of the service. Such are the facts, and the advertisement to which we have referred must be read by the light of these facts.

THE SMALL-POX AT KEIGHLEY.

The writer of two very sensible letters in the *Leeds Mercury* on "Anti-vaccination Fanaticism" opportunely and forcibly draws attention to the fact reported by the Registrar-General of the great mortality from small-pox in Leeds and Keighley. Three or four millions of people in London just now are enjoying almost absolute immunity from death by small-pox—one of the most horrible modes of death. It is not so with the much smaller population of Yorkshire. They have had in the last quarter twenty-eight deaths from small-pox, of which twenty-five have occurred in Leeds and Keighley. It must delight the hearts of Mr. and Mrs. Hume Rothery to know that small-pox thrives at Keighley, for it is a part of the strange fanaticism of anti-vaccinationists to have as much kindly feeling to small-pox as they have horror at the very thought of vaccination. The Keighley Guardians have at last been compelled, strongly against their inclination, as we may suppose, to give way to superior authority. At a meeting of the Board on Wednesday a motion was carried, with but four dissentients, that the time had arrived when no further resistance to the writ of *mandamus* should be made by the members, but that they accept the decision of the Court of Queen's Bench. A further motion was then proposed that the vaccination officers of the union be instructed to produce their books at the next meeting, with a list of defaulters, with a view of carrying out the compulsory clauses of the Act. This was also carried, the chairman and two others only voting against it. We hope to see shortly a diminution of small-pox in Keighley.

THE UTERUS OF HARRIET LANE.

At the meeting of the Obstetrical Society, held on Wednesday last, Dr. Alfred Meadows read a note containing a description of the uterus (supposed to be that of Harriet Lane), which was submitted to him for examination, and with reference to which he gave evidence at the trial of Henry Wainwright. It seems that the organ measured at the fundus one inch and three-quarters in width, the canal was two inches and a half in length, and the uterine walls of unusual thinness, one measuring rather less and the other rather more than a quarter of an inch in thickness. The os uteri had been injured and its character destroyed by post-mortem examination to such a degree as to render it impossible to discover its original condition. The inner surface of the organ presented a convex appearance, an appearance generally met with in the virgin, but not believed to exist in a uterus which has been gravid. From these characters Dr. Meadows thought it impossible to form a positive opinion with regard to the existence of a previous pregnancy, though he was inclined to the opinion that the organ was nulliparous. Owing to the scientific as well as public interest of the point in question, the discussion of the paper was postponed until the next meeting of the Society, to be held in January.

RESEARCHES ON MECONIUM.

Zweifel (*Archiv für Gynæcol.*, Band viii.) has recently investigated the contents of the large intestine in stillborn children, and has made the interesting observation that they contain hæmatoidin-crystals, which present the characteristic reaction described by Gmelin—namely, that the chloroform extract when evaporated yields bilirubin crystals. The crystals of hæmatoidin and other morphological constituents of meconium are no longer discoverable in the yellow evacuations. The chemical constituents found in meconium are biliverdin, bilirubin, the biliary acids, cholesterin, mucin, traces of formic and other volatile as well as some non-volatile fatty acids. No grape sugar, glycogen, paralbumen, leucin, tyrosin, albumin, peptone, nor lactic acid could be found. The amount of water in meconium was 80 per cent.; the ashes formed 1 per cent.; the fatty constituents 0·772 per cent.; and the cholesterin 0·797. Examination of the ashes showed, in contrast with the fæces of adults, a high proportion of sulphuric and a small proportion of phosphoric acid.

THE FREE MEDICAL SCHOLARSHIPS OF EPSOM COLLEGE.

The acting treasurer of the fund designed to establish these free scholarships, which are limited to the fifty foundationers after they have matriculated in the first class, University of London, has been visiting Liverpool and Manchester with the object of bringing their claims before the profession and the public. Dr. Carr has, we understand, been well received and very successful in his mission both among medical men and the wealthier classes. We are acquainted with few objects which have stronger claims on the truly charitable than these free scholarships, which give a helping hand to the orphan in order that in due time he may provide for himself. We would, therefore, hope that all who are able to contribute should lose no time in doing so, in order that the fund, still wanting £2000, may be completed.

DELIGATION OF THE CAROTID ARTERY FOR NEURALGIA OF THE FACE.

At the annual meeting of the doctors of Gräz, Dr. Patruban read a paper on this operation, in which he offered no theory as to the mode in which it acts, but grounded his defence of the operative measure on the results obtained. He proposes to operate in this manner when all other means have failed, and the patient insists upon relief at any cost. He himself had tied the carotid artery under these circumstances thirteen times, and had never noticed any of the symptoms mentioned as often occurring, such as cerebral congestion, vertigo, double vision, squinting, &c. The idea of the operator had been gained by the relief obtained, in some cases, by simple pressure of the carotid. The author added that no accidents need be feared if the operation is well done.

It has probably struck some of our readers, who are or have been in one of the services, that it would be most desirable to offer medical officers of the army and navy greater incentives to prosecute original work. There are honourable exceptions on land and on sea, but it must be admitted that the ruck of surgeons in both services, after admission, settle down into a somewhat somnolent performance of the actual duties demanded of them, and interest themselves but little in the progress of medicine and surgery. Many who perhaps consider that there is little inducement to work at present would, we have no doubt, be stimulated into exertion by the prospect of adequate rewards. We are led to make these observations by the recent announcement of the award of the Gilbert Blane gold medals. These prizes founded by the late Sir Gilbert Blane, Bart., were this year bestowed on Fleet-Surgeon T. J. Haran, for his Journal of H.M.S. *Glasgow* in 1874, and Fleet-Surgeon R. Eustace, for his Journal as Staff Surgeon of H.M.S. *Himalaya* for 1873. In accordance with the bequest of the founder, the medals are given by the joint concurrence of the Director General of the Medical Department of the Navy, and of the Presidents of the Royal College of Physicians and the Royal College of Surgeons.

At the late meeting of the Social Science Congress at Brighton a paper was contributed to the Public Heath Department by Mrs. M. A. Baines on "Some Unsuspected Sources of Infectious Diseases," which is now published in the form of a pamphlet. Mrs. Baines is a prominent lady sanitarian, whose facile pen has for some years been devoted to the cause of domestic sanitation. Her last contribution, which evinces considerable acquaintance with some of the conditions by which disease is generated, brings especially under notice those frequently unheeded evils, pig-tubs and dustheaps. Mrs. Baines also sensibly and opportunely points out the danger which may be incurred by sending clothes to be washed at the homes of the very poor, where the presence of disease is the rule rather than the exception, and expresses her opinion that laundries should be subjected to sanitary supervision. Ladies desirous to find a "mission" may with advantage peruse Mrs. Baines's works.

The introductory lecture in connexion with the commencement of the session of the Rotundo Lying-in Hospital, Dublin, was delivered last week by Dr. Lombe Atthill. After dilating on the great facilities of obtaining a thorough knowledge of obstetrics enjoyed by the students of the institution, the lecturer compared the short period of six months, which is deemed sufficient in which to study not midwifery alone, but also the nature, symptoms, and treatment of the large and complex class of diseases which are peculiar to females, with the three years ordained for the clinical study of medicine and surgery, and contended that it would require unremitting attention on their part to attain even a moderate proficiency in that short time. "The mass of students," said Dr. Atthill, "go forth into practice absolutely ignorant of these subjects — i. e., diseases of women,—and lamentable results consequently follow."

At a General Council of the University of St. Andrews on the 26th ult. Dr. B. W. Richardson was elected assessor, the office having become vacant by the resignation of Mr. Patrick Anderson. We congratulate the University on the election. Dr. Richardson is not only a distinguished physician and *savant*, but is conversant with Parliamentary business—an acquisition decidedly necessary to the exercise of the office. At the same meeting a desire to introduce certain innovations was manifested, and a resolution to appoint a committee to consider the expediency of obtaining entrance examinations in connexion with the University was unanimously carried.

The recognition by the Glasgow University of the teachers of the Andersonian has been persistently urged for some time past. We are glad to find that, at a recent meeting of the Glasgow University Court, it was resolved to recognise the lectures on Surgery delivered by Dr. James Dunlop in Anderson's University as qualifying for graduation.

Dr. Taaffe, medical officer of health for Brighton, has just issued a report of the health of the town during the last quarter. The annual death-rate in the period was 18·7 per 1000 of the estimated population. The mortality of children under five years old was 42·2 per cent. of the whole deaths. Of 61 infants who died of diarrhœa it was ascertained, by a special inquiry into the methods of feeding which had obtained, that 11 only had been nursed by the mother. The rest were fed by the various artificial foods, such as arrowroot, corn flour, condensed milk, &c. It is pretty clear that an immense amount of infantile fatality in this country is due to improper feeding and inadequate nursing. Dr. Taaffe gives some interesting details of a special house-to-house inspection which was made. It was found that in a great number of houses the interiors were connected, directly or indirectly, with the drains and sewers. No less than 420 of the best class of houses proved to be so defective. In 469 instances the house and closet were supplied from the same cistern with water, while in 173 houses the closet had no regular water-supply at all. These revelations must cause surprise, and cannot but injure the reputation of Brighton.

According to a military contemporary, enteric fever has recently prevailed in the 1st battalion of the 12th Foot at Kinsale. We understand that the outbreak in question was of a sudden and severe character, the greater number of cases of the disease having made their appearance within a comparatively limited period. The insanitary state of the barracks is blamed for the outbreak. The troops were at first placed under canvas, but have since been removed to Cork. Several of the cases proved fatal, but the disease has now ceased.

A St. Petersburg paper informs its readers that during the past year 171 pupils received instruction in the Female Medical College established in the capital of the Russias. Of these 102 are noble, 17 are daughters of merchants, and 12 of clergymen, the remaining 24 belonging to other classes of society. It would appear that the young ladies are extremely diligent in the pursuit of knowledge, and in especial display a marked predilection for dissecting-room work.

Mr. Robert McDonnell, F.R.S., surgeon to Dr. Steevens' Hospital, has announced his intention of being a candidate for the Vice-Presidency of the Royal College of Surgeons in Ireland at the next vacancy in June. Mr. McDonnell is well known, not only as a skilful surgeon, but also as a physiologist of no ordinary attainments. Mr. Ledwich's name has also been mentioned as a probable candidate, but we believe we are correct in stating that the announcement is premature.

We have received a copy of the seventh series of *Vanity Fair* portraits, which fully maintain the reputation created by the previous editions of the albums. Their scope is now pretty well known. We observe that Sir W. W. Gull, Bart., Mr. Lyon Playfair, M.P., and Mr. W. H. Russell of *The Times*, have places in the present series.

Mrs. Morison, widow of Mr. Alexander Morison, of Bognie and Mountblairy, has carried out his expressed wishes by erecting and completely furnishing a Cottage Infirmary at Forgue, Aberdeenshire, at a cost of nearly £2000, and endowing it with £2000.

Dr. J. C. Bucknill has resigned his appointment of Visitor in Lunacy. The salary of the vacant office is £1500 a year with travelling expenses.

The Lords of the Admiralty have placed H.M.S. *Clio* at the disposal of the authorities of the *Cornwall* school-ship, and she will in a few days be brought round to Gravesend, and take on board all the healthy boys. They will remain on her probably for some weeks, as the future of the *Cornwall* is still undecided. The patients at the Seamen's Hospital, as well as those on board the Corporation's hospital-ship *Rhin*, are, with two exceptions, all progressing favourably.

Messrs. Sampson Low and Co. have now issued Vol. V. of Ziemssen's "Cyclopædia of Medicine." No sequence is preserved in the issue of the volumes, as Vol. IV. has not yet appeared, while the last volume was the tenth. This, however, does not detract from their intrinsic value, or from the admirable manner in which the publishers have done their work.

We made a slight inadvertence in stating last week that Dr. Sedgwick Saunders had been placed on the Commission of Lieutenancy for the City of London. We were misled by a newspaper paragraph. Dr. Sedgwick Saunders has been a Commissioner since 1868.

REPORT
OF
The Lancet Commission
ON
LUNATIC ASYLUMS.

The purposes of the present inquiry are:—

To ascertain the general character and efficiency of the provisions made for the Insane in Asylums, and the conditions of their daily life;

To discover the measures, and, as far as may be possible, to formulate the system, of treatment adopted for the cure of remediable, or recent, and the relief of incurable, or chronic, cases;

To collect and collate statistics of cases occurring within the last ten years, at the asylums visited, with a view to estimate the results.

It is believed that such an inquiry will help to furnish the profession with the much-needed data for personal opinion on many urgent questions, relating to the treatment, in public and special institutions, of patients labouring under the various forms of mental disease. It should also contribute to the sum of evidence required to determine moot points with respect to the diverse methods of treating insanity. And it may do some service by exposing, and thereby tending to the removal of evils and the redress of grievances affecting the insane, if any should be found to exist.

The inspection will be conducted with the approval, and it is hoped the co-operation, of the medical superintendents and officers of asylums.

The area of the inquiry, and the number of asylums visited, will be determined by the results obtained, and the extent to which responsible managers of these establishments may be found willing to submit their arrangements to the scrutiny it is desired to institute.

The exigencies of space for publication will necessarily limit descriptive detail in the reports presented, but no point of moment or interest will be overlooked in the inspection, and the general results will be given as concisely as possible.

No special order will be observed in the sequence of Reports, but the same general arrangements of topics will be followed as closely as may be convenient in each statement.

BROOKWOOD ASYLUM.

THE HOUSE AND ARRANGEMENTS.

This is the second asylum for the county of Surrey. It was opened on June 17th, 1867, to meet the pressing need of fresh cases which could not be received at Wandsworth. It is much to be regretted that, being provided with all the most approved appliances, Brookwood was not jealously kept to its true purpose as a hospital for the cure of new cases, instead of being at once crowded with chronic cases removed from other asylums and licensed houses. This economic blunder is now visited on the county by an urgent demand for a third asylum; a need which will crop up about every seven years, at the present rate of increase of insanity in Surrey, unless the policy is changed. In design and construction the establishment evinces considerable care. It is the boast of Her Majesty's justices for the county that the architect visited the best asylums in England and France before preparing his plans, and that this course was pursued "for the first time in England." The result is a series of buildings of by no means repulsive aspect, pleasantly situated on an elevated site about one mile from Brookwood, and three miles from Woking station, on the South-Western Railway, in the parish of Woking. The asylum, as it exists to-day, is composed of the original blocks, to which additions have from time to time been made, and some new and very superior buildings which have only just been completed. The story of the first construction has for its moral the economic wisdom of appointing the medical superintendent of an asylum in time to secure the advantage of his practical experience in aid of the architect. It was not long before the superintendent of Brookwood discovered defects and deficiencies in the edifice which it became his object to remedy. For example, the common error of limiting the accommodation so that an almost immediate increase becomes necessary, and that of forgetting the requirement of proportionally larger space on the female side of such an institution, were committed in the construction of this asylum. The advice of an experienced superintendent would have prevented these mistakes, and others equally unaccountable. The area of room allotted for day use was inadequate, only 19 superficial feet per head, inclusive of epileptics, all told—or 24 feet inclusive of corridors and passages—instead of 35 or 40, being available for the purpose. This deficiency was pointed out in the earliest report of the superintendent. But the faults of arrangement at the outset were not due to parsimony on the part of the county authorities, and they have been compensated by spirited and wise liberality in the subsequent conduct of affairs. The original aim seems to have been to give the asylum a thoroughly domestic character, and in this its designers were successful, perhaps too much so, as in the construction of dormitories allowing only 550 cubic feet of air for each patient. The old buildings are throughout not sufficiently commodious. The ceilings are too low, the corridors narrow, the staircases tortuous, and the whole constructionally cold and comfortless. By dint of building out, adding bay windows, and opening arched communications—where the safety of party walls would admit—from the wards into adjacent corridors, the superficial space has been raised from 19 to 39 feet per patient; and with the aid of wall-paper, colour, and floor-cloth, the interior has been made to assume a bright and cheerful aspect, exceedingly creditable to the ingenuity by which overwhelming difficulties have been overcome. The new buildings are incomparably better, not less homely, and, including the furniture, which has for the most part been made in the asylum, not more costly than the old. Indeed, they leave little to be desired as a healthful and appropriate residence for the insane.

The visitor to Brookwood will be strongly impressed by its simple and homely characteristics. There is nothing prison-like or Poor-law-stricken in the exterior. No high walls, massive casements, gloomy iron bars, or other tokens of restraint, inspire repugnance. The place looks like a cheery hamlet of almshouses, with its winding paths, undulating pleasure-grounds, well-planted shrubberies, and picturesque detached chapel, to which the inmates repair for service every Sunday, with all the charm of rural "church-going." Within, the institution wears an air of quiet repose and cheerfulness. The day-rooms are fitted with plain and convenient furniture, embellished with stands of flowers, plants, and aviaries, and provided with pianos, bagatelle-boards, cards, dominoes, draughts, books, and pictures. The walls are decorated with coloured prints, in cheap but elegant frames; and the apartments are so arranged as to produce a most agreeable impression on the mind of a stranger, with doubtless a corresponding influence on the residents. The patients, when not in the grounds or work-rooms, sit about among the plants or at the little tables, in groups or alone, as the mood takes them, contented and enjoying as high a sense of liberty and pleasure in life as their cases admit. The melancholic are less depressed, and the turbulent less excited, for the interesting and genial associations with which they are provided. The surrounding objects divert, as far as possible, the mind of the patient from that brooding self-consciousness which constitutes one of the most formidable obstacles to recovery in curable cases, and the severest sorrow of the confirmed lunatic's dreary existence. The fireplaces are open, like those of ordinary houses, and not fenced off with grim guards suggestive of mischief. The chimney-pieces are prettily decorated with inexpensive ornaments, and the pictures on the walls are hung within reach of the patients, but scarcely anything has been injured or disturbed. The policy has been to place the inmates of Brookwood Asylum as nearly as may be amidst the surroundings of sane life, and then to treat them as children under a perpetual personal guardianship. They are neither provoked by obtrusive prohibitions, harassed and incited to mischief by that suggestive sort of protectorship which the disordered intellect always distorts into an ever-present temptation to wrong-doing, nor left dependent for immunity from accident upon mechanical safeguards. Attendants have no excuse for neglect of constant supervision, because there are no appliancesupon which they can rely in the abstinence from duty. They *must* watch, and, recognising the impossibility of shirking personal responsibility, their task is habitually performed and becomes easy. It must not, however, be supposed that any requisite precautions against peril are omitted. From the locks on window-frames to prevent their being thrown up to a dangerous height, to an ingenious arrangement by which a continuous rush of water is made to denote the presence of any patient in a water-closet, we found all known and many novel contrivances for the safety of the inmates provided, and, which is equally important, kept in working order. The dormitories are so arranged as to give the attendants on duty efficient command of the beds. They can see and hear all that is going on. The rooms are lighted, for the most part, by gas-jets outside the apartments and showing through panes of glass. The bedsteads are of birch, in preference to iron, fitted with battens—except for the epileptics, who are laid on webbing,—and in all cases supplied with a hair mattress and straw palliasse. Great care has been taken in the construction of the furniture, and it would be difficult for an epileptic or suicidal patient to fall into danger. Every ward is amply provided with requisites for the inmates. The arrangements for washing and dressing are commodious, and comfort is considered, down to the detail of placing a bottle of filtered water for drinking for each dormitory. It would be better if the bottles were replaced by small filters. It is in minor matters like this that the efficiency of management most clearly expresses itself.

The provisions for recreation are very considerable. The airing courts are tastefully laid out, with especial regard to pleasure and safety. Instead of the regulation walks and formal grass plots, each court is a garden. Sun-shades, arbours, grounds for croquet and other games, tell of the wisdom no less than the sympathy with which all has been planned. A large recreation hall has been provided, in response to the request of the medical superintendent, with every convenience for theatrical and other entertainments, and it is seated with benches of admirable construction, made in the asylum. There is a well-arranged cottage hospital, wholly detached from the main building, and with all its offices self-contained. This, also, is a recent addition. It will be used as a residence for convalescent cases which it is desirable to separate from the general body of the patients, in times of health, and applied to its special purpose in case of need. The ordinary infirmary wards are well situated and appointed; and with special forethought a detached mortuary, with post-mortem room and all conveniences, has been erected in an obscure part of the grounds, approached from the main buildings by a masked path. This is an excellent feature. The asylum generally is well ventilated by wall-shafts in the wards and in the single rooms, which are sufficiently though not very numerous and suitably furnished. A perforated plate near the floor admits cool air, and is protected with sliding shutters. An opening just below the ceiling allows the egress of foul air. There are no "strong" or padded rooms in the institution. The system of treatment adopted does not recognise or require such appliances; but of this we shall speak presently.

The boundary path of the asylum provides a walk of nearly three miles within the grounds, and the use of sunk walls instead of high fences secures the great advantage of an unbroken view from every point. The prospect is interesting and extensive. The Mid-Surrey hills, the Frimley ridges, and the Basingstoke canal which bounds the estate on the south, are pleasing objects in the landscape. Much of the ground on which the buildings stand has been made by transfer of materials, and considerable skill has been evinced in landscape-gardening and general culture. The Bagshot sands, with gravel and clay, underlie a thin and poor soil, which, however, has been greatly enriched by utilising the sewage of the asylum. The farm is well managed, and of great value to the establishment, both as supplying healthful occupation to a large class of male patients and on account of its produce. The residences of the medical superintendent, the chaplain, the farm bailiff, and the gardener are detached. The two latter have been adapted for the reception of a limited number of patients draughted from the principal buildings, and forming little working communities, under especially sociable influences which are highly appreciated and of great value to the cases so disposed. The water-supply has from the outset constituted a great difficulty. The quantity has been eked out by drawing from the adjacent canal. Every precaution has been taken to ensure purity by filtration, and repeated analyses by competent referees show that the quality has been fairly good; but the source is wholly *surface-water*, and we are glad to be assured that measures will shortly be taken to obtain a better supply by sinking an artesian well. This will need to be carried to a considerable depth—we fancy greater than the experts consulted estimate,—and the works must be proportionately expensive; but the need admits of no palliation, and will not tolerate further delay. The sewage, as we have stated, is "utilised," and the drainage appears satisfactory. The original arrangements were obviously defective, but very much has been done to improve matters; and, under the present management, there is little doubt that the necessity for amendments, being clearly recognised, will be fully met.

The daily life of the patients is well ordered. The time is filled up without being excessively burdened with engagements. There is neither the measured haste of an oppressive industrial *régime*, nor the monotony of prison discipline. A kindly and sympathetic intelligence seems to hold the reins of government in perpetual control, and its modifying influence is apparent at every point of the system. The feeble and infirm patients are not ruthlessly routed from their beds, while those who would drift into habitual inertia are judiciously urged to activity by encouragement and example, instead of being irritated and coerced. Those who have witnessed the results of a dissimilar practice at some asylums will not fail to recognise how much the substitution of this more considerate method involves and implies. The service of the attendants is as orderly and effective as a well devised system of checks and counter-checks can make it. The remarkably small number of "wet" and "dirty" cases reported, observed by the Commissioners in Lunacy from time to time, or recorded in the books, which we were allowed to inspect, speaks well for the attendance. The number of patients "raised" bears significant proportions to the instances of misadventure. The personal responsibility of the officials is clearly well enforced, and the principle of minimising safeguards and appliances, which too commonly prove excuses for neglect or carelessness, is in large measure successful, and productive of watchfulness and diligence. The patients are suitably clothed, but the depressing effect of a uniform, especially marked in the case of females, is wisely avoided. The dietary is sufficient and well varied. It includes a liberal supply of vegetables and fruit. An occasional fish dinner has recently been added, and one of Australian meat, admirably prepared, is greatly relished. Patients are carefully weighed every month, and the results recorded, so that any failure of nutrition requiring a change of food is promptly detected. The allowance of extras is governed solely by the needs of the special case for which they are prescribed. The arrangements for the health and comfort of the inmates may be fairly summed-up in the language of one of the medical reports: Brookwood Asylum is a hospital for the cure of curable cases, not a huge depôt for chronic cases. The efficiency of the ordinary medical superintendence was seriously and suddenly tested by an outbreak of small-pox in 1871. The expedition with which the epidemic was stamped out proved the completeness of the sanitary system and the vigour of the staff. The provisions against risk from fire, always of the greatest importance in an institution of this class, are respectable. Hydrants are placed on all the principal floors and levels, and connected with a large tank at the summit of a tower. This was not as well filled *as it ought always to be* when we visited the asylum; but the point is not overlooked. There is a fire-engine and a fire-escape in an out-house, and a corps of firemen has been organised under the command of the engineer of the asylum, and is regularly drilled. A periodic inspection by Captain Shaw would be of service. We commend the suggestion to the Visiting Committee. The cost of patients is now only ten shillings and sixpence a week per head, inclusive of all charges and expenditure. We come next to the

Treatment.

"Insanity is so essentially a disease of debility," remarked the medical superintendent, in his first annual report (1868), "that, as a necessary starting-point to its successful treatment, a good and generous diet is required." This, as we have stated above, is provided. The general discipline is equally satisfactory. Courtesy, patience, thoughtfulness, watchfulness, truthfulness, and sympathy are the virtues expected and required from officials in their daily dealings with the sane; and the cultivation of these qualities is enforced by an admirable code of rules of conduct, which every attendant is obliged to study and obey. Great care is exercised in the appointment of suitable attendants for the wards—1 to 10·5 patients on the male side, and 1 to 12·6 on the female. As far as we can judge from appearances, and from the condition of the wards, which commonly affords a fair indication, the service is fairly satisfactory. This impression is confirmed by careful examination of the Commissioners' reports, and by the measures taken in cases where the attendants have failed in their duty. A wise discretion has been shown in choosing persons who have not previously been engaged at other asylums, where they may have picked up, not only "experience in the *management* of the insane"—at best a very equivocal qualification,—but acquired habits of expertness in the evasion of rules and perfunctory performance of the duties required of them, with a facile skill in deceiving those in authority over them and shifting the obligations of direct responsibility. A very complete and apparently effective system of registers and reports is in force, and, if fully carried out, the details, symptoms, and behaviour of each case must be brought under the cognisance of the medical officers. We are assured that this system is tested at all points and checked by observation, and the demeanour of the patients certainly conveys the impression that they live as orderly, healthful, and pleasant lives as their condition admits. The fundamental principle would seem to be to place every patient as much at ease as his or her state will allow, and to obviate the feeling of restraint at the same time that provocation to displays of temper and excitement are carefully avoided. The physical condition of each patient on reception is minutely examined and noted. In the case of every person sent in from a workhouse, a special statement of the condition in which he reaches the asylum is forwarded to the local board of guardians. Since this procedure has been adopted, a marked improvement in the method of removal and in the state of such patients has been observed. The bodily health of a patient is the object of primary care. As regards the general method of treatment, the following passage, which we extract from the report of the medical superintendent at the close of 1874, is significant:—

"Mechanical restraint has not been employed since the opening of the asylum, and there has been no instance of seclusion since the year 1870."

Previous to 1870, "seclusion"—i. e., placing a patient in a room alone, and locking or otherwise securing the door—was adopted in seventy *instances*, distributed over sixteen *cases*. For example, in 1867 there was a case of puerperal mania of unusual severity. Opium had been largely administered before admission. The patient was secluded for short periods thirty-six times. Eight other cases during the same year were secluded, in all, thirteen times. The asylum was opened on the 17th of June, and to the 31st of December—

in 1867	there were	9	cases, comprising	49	instances.
„ 1868	„	3	„ „	15	„
„ 1869	„	2	„ „	4	„
„ 1870	„	2	„ „	2	„
		16		70	

The Report of the Commissioners in Lunacy, dated June 17th, 1870, contains a significant paragraph:—

"Upon this subject (seclusion) Dr. Brushfield states, as the result of his experience and observation, that special care and treatment in the open wards is preferable in all cases of violent excitement to seclusion. He is strongly of opinion, that not only is the benefit to the patient thereby promoted, but the effect is to ensure vigilance and the more efficient performance of their duties on the part of the attendants."

The circumstances, that the asylum was a new one undergoing continual alterations, and that the staff of attendants was scarcely in working order, together with the exceptional severity of some of the cases occurring before 1870, must count for much in the explanation why the medical superintendent did not earlier act on his personal convictions. We do not understand from Dr. Brushfield that he entirely abandons "seclusion" as a method of treating excitement; but the cases in which it might, in his opinion, be of use are so seldom met with that shutting a patient up alone to play out his passion in a padded room, or to "calm down" his excitement in solitude with nothing but the demon of his own disease by way of companionship, is practically eliminated from the system of treatment. Next to the folly of attempting to overcome violence by violence, so forcibly exposed by Dr. Conolly years ago, or of seeking to dispel deceptive persuasions by deceit, this trouble-saving artifice of seclusion is conspicuously irrational, and might well be wholly discountenanced. The method now adopted with particularly excited cases at Brookwood is to place the patient in a single room, of small size but in no other way peculiar; to tell off one, two, or, if necessary, more attendants for the special duty of quieting and, with moral influences, protecting and controlling him; and then gradually withdraw the demonstration of strength as the excitement subsides, until a single attendant sitting outside the room with the door open will suffice for effectual guardianship. Scarcely any cases so controlled call for physical force, and, when indispensable, it is employed without mechanical appliances, and with studious calmness and moderation. All pressure on the chest and body is peremptorily interdicted. During our visit we had the opportunity of seeing a woman of violent temperament and in considerable excitement so treated. In a padded room she would have been furious. We have known less turbulence produce wild havoc in a chamber elaborately padded from floor to ceiling. In this instance the patient walked about good-temperedly, leaving and re-entering her room at pleasure, always closely, but not unpleasantly, attended by the official on duty, and was quite content to vent her impulses in an occasional outburst of vehement chattering or loud singing. In the absence of anything to exasperate the emotions, or to quarrel with, her excitement was kept at its lowest point, and therefore incomparably less injurious to the brain and morbid will, and much more easily restrained by suasive influences. A less boisterous case was stamping with harmless energy in an open ward, and evidently passing through a paroxysm under the watchful eyes of attendants and the amused gaze of quiet inmates, many degrees below the fever-heat of conventionally restrained madness.

What may perhaps be designated the negative treatment of insanity is wholly of this class at Brookwood. Everything is so ordered as to tone down excitement and spare strength. Exhaustion is never desired, much less courted, or even intentionally brought about by the measures adopted, with a view to reduce the more formidable and troublesome symptoms of mania. There are no punishments properly so called. The shower-bath is *never*, we are assured, under any circumstances, employed as a measure of discipline. When required for physical treatment, it is especially explained to the patient that the reason of its use is purely medical, and he is generally induced to enter the bath himself and pull the valve-string "for his own benefit." The only correctionary discipline takes the form of a deprivation of some privilege or enjoyment not essential to health, and this can never be administered except by direct personal order of the medical officer. The attendants have no "power," and nothing is left to their discretion.

The positive remedial treatment is essentially moral and mental. Patients are provided with suitable and interesting employment, and sedulously diverted from their own broodings phantasies. The out-door labour and the works carried on within the asylum are so arranged as to afford a varied source of interest. The patients are allowed to work *with* the attendants, not to perform a task *under* their surveillance. It was difficult, in many cases impossible, to tell which were the attendants and which the patients, so cheerfully did the two classes work in companionship. More purely diverting appliances, such as stage-plays, concerts, conjuring *séances*, panoramas, balls, illustrated lectures, and exhibitions of divers kinds, are employed, systematically and at short intervals, as means of taking the mind out of itself and leading it back to normal trains of thought and methods of thinking, through new channels. The asylum band, composed of the attendants and officials, numbers sixteen. Neither pains nor expense are spared to perfect this valuable repertory of mental remedies. No means of reaching and swaying the mind are neglected. The patients are never left without restorative and healthful agents at work around and upon them; and it is by the continuous operation of such constraining and persuasive mental influences that the cure of curable cases is sought to be effected. Of course the chronic cases, and those complicated with epilepsy and general paralysis, are not susceptible of remedy by mental treatment, if at all; but even in these deplorable instances much is gained by the ameliorating though transient influences exerted. This, however, brings us to the consideration of

RESULTS.

The subjoined table will serve to place the medical statistics of Brookwood Asylum, from the date of its opening to the end of 1874, conveniently before the reader. It may be premised that with the additional accommodation afforded by the new buildings just completed, the institution will be able to house 1060 patients, instead of 633—the largest average number resident any year during the period to which these returns relate.

The summary is reproduced, with modifications, from the returns required by the Commissioners. Additional particulars embodied in the fifth column have been obligingly supplied by the medical superintendent from the case-books. The first point that calls for comment is the very small proportion—26·49 per cent.—which the "curable" cases bear to the total number of admissions. This is most unfortunate. As far back as 1871 Dr. Brushfield called attention to the disadvantage of allowing a "hospital for the proper medical treatment of recoverable cases" to "assume more the character of a hospital for incurables." The appropriation of special establishments for chronic cases, under the control of the Commissioners in Lunacy—not, as is the case with some of the asylums professedly set apart for that purpose, under the Local Government Board, and classed as *workhouses*,—is an expedient which cannot long be delayed. The very extraordinary course pursued with regard to ex-criminals, who are now discharged from the criminal asylums into the county houses, to the serious detriment of the latter, increases the urgent need of reform in this direction. What we have to say on this point will, however, come better at the close of our remarks, when the facts are all before the public. The small proportion of curable cases is due to the large number of general-paralytics and epileptics at Brookwood, a circumstance especially to be regretted when the efficiency of the institution as a hospital is considered. The proportion of cures to curable cases —65·39 per cent.—which constitutes the best measure of success, is satisfactory. The percentage of deaths on the average number resident is by no means high, but must be further qualified by the number of deaths whose immediate cause was general paralysis. This incurable malady accounts for 31·4 of the total mortality, or 140 out of 451 deaths in all, from the opening of the asylum on June 17th, 1867, to Dec. 31st, 1874; which gives a gross proportion of deaths of 29·94 on the total number of admissions—1740—for the same period. The percentage of "recoveries" on total admissions is 28·06. But the percentage of cures upon "admissions" affords no useful indication as to the results of treatment. Obviously the outcome must depend upon the kind of cases admitted, and mere numbers show nothing to the point. Calculating the percentage of cures upon cases "deemed curable" supplies a better inference. Although medical superintendents differ widely as to the cases they deem hopeful, each asylum is tested upon the basis of its own prognosis. A comparison of the columns showing, respectively, the number of "recoveries" and "deaths" within six months of admission will enforce the expediency of dealing with *recent* cases apart and promptly, for these only are "hopeful." It will be seen that the prognosis of curable cases at Brookwood at the close of the year 1874 gave only 37 as hopeful. We reserve general remarks until the state of our inquiry renders it possible to compare the results obtained at other asylums. Our warm acknowledgments are due to the great courtesy and frankness of the excellent medical superintendent, Dr. T. N. Brushfield, and his assistant medical officer, Dr. James L. Barton.

* This asylum was not opened until June 17th, 1867.

† This percentage is upon the total of "curable" cases remaining on Dec. 31st of the previous year (11th col.) and those admitted during the current year (5th col.)

‡ These were patients bitten by adders in the grounds.

SUPPLY OF SUBJECTS FOR DISSECTION.

LOUD complaints are made by almost all the teachers of anatomy in London of the scarcity of subjects for dissection. When, in 1871, Professor Humphry, of Cambridge, interested himself in securing some changes in the Anatomy Act of William IV., whereby the period within which the certificates of interment to be transmitted to the Inspector of Anatomy was extended from six weeks to a period not exceeding six months, it was thought that anatomical teachers would be able to collect and preserve bodies during the four months prior to the commencement of the winter session, and by that means obviate the difficulties that had been previously experienced from the want of bodies. Unfortunately the experience of the last three years has shown that the alteration has not been productive of as good results as were anticipated. A considerable difficulty has been felt in preserving bodies in a fit state for dissection for three or four months; but, as we showed in the Report on the Preservation of Bodies, in October, 1872, this difficulty may be overcome to a great extent, if only the Inspector of Anatomy could be encouraged to make an effort to supply an adequate number of bodies. It is an anomalous state of things that, in a community numbering over three millions and a half, anatomical study should be thwarted for the want of material. Thousands of unclaimed persons, whose bodies should be available for anatomical purposes, die in London every year. But the fact is that it seems to be no one's business in particular to look after the supply of subjects, and therefore the work is not done. The Inspector of Anatomy has clearly proved that it is no part of his duty, and the Poor-law officials are not always actuated by a desire to advance scientific pursuits. Those teachers who recollect the excellent administration of Sir Rutherford Alcock must sympathise with the teachers of anatomy of to-day. Although we have now entered upon the third month of the session there are in the large schools many first, and even second, year's students who have not been able to procure one part for dissection.

In reply to our inquiries, the teachers of anatomy in the metropolitan schools have kindly supplied us with the following information respecting the supply of subjects and the number of *bonâ fide* students in the anatomical classes:—

	Subjects.		Students.	
	Total.	Inspector of Anat. since Oct. 1st.	First year.	Total.
Guy's	28*	10	93	240
St. Bartholomew's	22†	6	108	225
University College	14	8	86	203
St. Thomas's	11	5	50	158
St. George's	9	5	43	83
King's College	6	3	32	80
Middlesex	5	4	38	72
London	12‡	10	35	71
Charing-cross	2	2	28	45
Westminster	4	1	12	26
	113	54	525	1203

---

* Eight post-mortem examinations had been held, so that only the limbs were available. Several were from the hospital, and four have been received this week. † Seven of these were from the Hospital.

‡ Two from the Hospital. This School is in a very populous district and a large parish.

There have been, therefore, from all sources, and including those preserved before the commencement of the session, 113 subjects supplied to ten metropolitan medical schools for the purposes of dissection this session, of which only 54 have been furnished by the Inspector since October 1st, while the total number of students desiring to dissect is 1203, of which 525 are first-year. It need scarcely be said that this supply is quite inadequate. As one body is generally allotted to six or seven students, we shall say seven, about 200 bodies should by this time have been supplied, because at this period of the session many students should have completed one part, and been far advanced in a second part, especially those students who are preparing for the January and April examinations.

It will be seen that we have not included St. Mary's in the above table. The reason of this is that we have not received a return from the lecturer on anatomy of that school. The main facts will not, however, be materially influenced by the omission of this school, which is, we hear, always kept well supplied with subjects.

Correspondence.

"Audi alteram partem."

ARMY SANITARY COMMISSION.

To the Editor of The Lancet.

Sir,—On the 24th November I asked you to be good enough to insert a statement of facts regarding the work of the Army Sanitary Commission. This statement was directed against charges of incompetency brought against the Commission on account of certain remarks of theirs on reports referred to them from India, in which they had failed to discover evidence of the spread of cholera by water poisoning. I was not then in a position to state what views the Commission had actually expressed, because the papers had not been published. They have, however, since appeared, and I can now state exactly what the Commission did.

A severe epidemic of cholera broke out in 1872 in the North-west of India, and the Government of India directed special local inquiries to be made by medical officers of the British and Indian armies at affected stations. This led to the production of reports on 108 outbreaks at 44 stations, the notes of which appeared in the report of the Sanitary Commissioner with the Government of India, which came before the Army Sanitary Commission in the usual way. At the same time Dr. Cuningham laid before the Commission a series of questions on these reports. The replies to these questions were first drawn up, and then the remarks on the reports, and it happened that both documents were sent to the India Office on the same day; the questions giving the answer in detail, the remarks giving merely the result. Had both documents been printed together in last year's India Office Report, the case would have been evident enough, but the remarks were published in last year's report, and the replies have just been issued.

The following is Dr. Cuningham's question, together with the reply:—

"*Question:* Is there anything in the evidence given in my report to support the idea that cholera was spread by a specific poison drunk in water?—*Answer:* Without prejudging the results of more extended inquiry, and supposing that every obtainable information on this subject during the epidemic of 1872 has been recorded, the Committee has been unable to discover any evidence in support of the conveyance of cholera infection in drinking water."

You will see that this gives a very different aspect to the action of the Commission, and had the facts all been printed at the same time, the recent attacks on the Commission in this matter would have been superfluous. As the case stood, however, it must in fairness be confessed that the terse expression in the remarks, "there is no evidence to sustain a current theory that cholera poison conveyed in water is the cause of cholera," although intended to be read in the light of the reply, when taken by itself, and without the reserves in the reply, looks like a decision on the whole case on the evidence as it stood. The reply gives the exact position taken by the Commission in the discussion.

I might stop here, but it appears to be only an act of justice to the authorities in India to state that they did make further inquiries by sending copies of the reports to all the medical and other officers who had supplied the information originally, with a request that mistakes might be corrected and any additional information inserted.

The result, as stated by the Sanitary Commissioner with the Government in India, in his report for 1873, is that "no mistake on any important matter of fact has been brought to notice, nor has any additional information of value been furnished."

I am, Sir, yours, &c.,

London, Nov. 27th, 1875. John Sutherland, M.D.

EFFUSED BLOOD.

To the Editor of The Lancet.

In reference to some remarks of mine in a clinical lecture you published the other day, on the various modes in which effused blood may be disposed of, will you allow me to relate the following case? It illustrates what must be, I think, a very uncommon course of events.

Some months ago I removed an encysted tumour, about the size of a filbert, from over the parotid gland of a girl aged fourteen. No vessel needed a ligature, and the edges of the wound were, of course, brought accurately together, and covered with a pad of lint secured by a bandage. After forty-eight hours, when the pad was removed, the wound looked well. Its edges were in close contact, apparently united, and there was no sign of separation of its surfaces, or of any untoward disturbance. But in the course of the next day or two, although the pad was carefully replaced, the wound was gradually raised, and the adjacent parts distended, by an effusion beneath them, so that it then looked very much as if the tumour were still there. From the absence of all signs of inflammation or of any disturbance, I was sure that this could not be pus—that it must be either blood or serum. The child declared that there was no pain, nothing beyond a little stiffness. On the third or fourth day, to avoid the risk of leaving any pent-up fluid, I introduced, through the middle of the wound, which readily yielded, a very fine probe. The point moved freely in a cavity, but nothing whatever escaped, and when it was withdrawn the end was stained with blood. The swelling remained, showing for some days no sign of decrease, but there was no further local disturbance of any kind. At the end of nine or ten days the sense of fluctuation was still so marked that I again introduced the probe, but with only the same result. The wound throughout its length was quite united; it looked perfectly well, but the swelling persisted, and gradually the parts around the wound became discoloured, as if bruised. I could not doubt that there was a mass of blood, more or less coagulated, beneath it, and of course I was much interested to see what would become of it. Would it at length be discharged, provoking suppuration, or would it slowly shrink, becoming absorbed, or might part of it become organised? I mentioned the case and put the question to several friends, and the unanimous verdict was that sooner or later it must come out. But it never did. After remaining with very little change, save wider and deeper discolouration, for a fortnight, the swelling very slowly began to subside, the sense of fluctuation passed away, the surface resumed its natural colour and outline, and at the end of a month or thereabouts evidence of an operation could not have been slighter. Indeed, after some weeks longer the scar was singularly faint, and I fancied that the slender linear depression which one can usually detect had been counteracted by the temporary distension.

Who would not have watched the progress of this case with intense interest? I was anxious, too, for a time, for I feared that suppuration might occur and leave an ugly mark, and in the majority of cases blood so effused would undoubtedly be thus expelled; but in a healthy child, healthy blood, lying in a nest of healthy tissue, was disposed of very quietly and in the simplest way. It provoked no mischief, and the little patient was never even conscious of its presence; and this although no special means were adopted to exclude germs, and I fear that I must, on more than one occasion, have introduced a few with my probe.

The atmosphere, however, must have had but limited, if any, access to this blood; for I have little doubt that before it was effused the lips of the wound had united; so that, although it was associated with a wound, it was really under the condition of blood extravasated in a bruise.

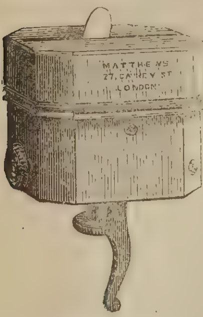
I am, Sir, yours truly,

Brook-street, W., Nov. 30th, 1875. WM. S. SAVORY.

AN IMPROVED SCARIFIER FOR INCISING DROPSICAL LEGS.

To the Editor of THE LANCET.

SIR,—Messrs. Matthews, the surgical instrument-makers, have lately made for me an improved spring scarifier for incising dropsical limbs. The instrument, a sketch of which is here given, is, in fact, a small cupping scarifier with a single blade. The blade is drawn back by a metal lever, and held by a catch until it is loosened by touching a brass knob. The length of the incision is about half an inch, and the depth is regulated by a screw which raises or lowers the brass cover through a slit in which the lancet makes its sweep.



The main advantage of this instrument consists in the fact that the incision, being made by the rapid sweep of the spring scarifier, is attended with much less pain than results from the slow incision with an ordinary lancet or from punctures made with needles. This instrument, with the semicircular sweep of its blade, is also preferable to one which I formerly used, in which the lancet was thrust straight forward by a spring. The incision made by the sword-like sweep of the one instrument is more rapid and less painful than the dagger-like thrust of the other. The instrument is so constructed that it can be easily opened for the purpose of cleaning the blade, which should be done immediately after its use.

I am, Sir, yours &c.,

Savile-row, Nov. 30th, 1875. GEORGE JOHNSON, M.D., F.R.S.

DEBATE ON MR. WELCH'S PAPER AT THE MEDICO-CHIRURGICAL SOCIETY.

To the Editor of THE LANCET.

SIR,—Will you allow me to correct in two particulars your able and otherwise very accurate report of my remarks in the above debate? I spoke in round numbers of 500 soldiers as being *annually* lost to the British service through diseases of the circulation. Of them 450 died or were discharged on account of heart disease, 50 on account of *aneurism*. In a later sentence I did not mean to imply that the *faintest* venereal excoriations were often recorded as syphilis, which would have been an exaggeration, but that they were recorded (contrasting in this respect with intemperance), and I then gave reasons for thinking that venereal sores were inaccurately classified, thus swelling the numbers of syphilis.

I am, Sir, yours faithfully,

R. DOUGLAS POWELL.

Henrietta-street, W., Nov. 30th, 1875.

BEQUESTS, &C., TO MEDICAL CHARITIES.—Mrs. Teresa Ann Carmichael, of St. Stephen's-square, Bayswater, bequeathed £300 to St. George's Hospital; £200 each to the Royal United Hospital, Bath, the Cancer Hospital, the National Hospital for Diseases of the Heart and Paralysis, King's College Hospital, and the Hospital for Sick Children; and £100 each to the General Hospital, Bath, and the Dental Hospital of London.

Medical News.

UNIVERSITY OF LONDON.—The following is a list of candidates who have passed the recent M.D. examination:

Crocker, Henry Radcliffe, B.S., University College.
Duncan, Andrew, King's College.
Eastes, Thomas, Guy's Hospital.
Philpot, Joseph Henry, King's College.
Sturge, William Allen, University College.
Yeo, Isaac Burney, King's College.

The following have passed the recent B.S. examination:—

FIRST DIVISION.

Hullard, Jean Arthur, B.Sc., University College.
May, Bennett, Birmingham General Hospital.
Maclean, Thomas Edwin, University College.

SECOND DIVISION.

Hobson, Lewis John, University College.
Jameson, Leander Starr, University College.
Rose, William, King's College.
Voelcker, George Henry, University College.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on Nov. 25th:—

Fonmartin, Henry de, Lying-in Hospital, York-road.
Mahony, Laurence Francis, Amherst-road, Dalston.
Roberts, Gordon Money, Finchley-road.
Stephens, Meredith Lloyd, Belper, Derbyshire.

The following gentlemen passed the Primary Professional Examination on the same day:—

Ernest H. Buckell, University College; Daniel Colquhourn and Arthur Greenwood, Charing-cross Hospital; Frederick Alexander Hyne, Guy's Hospital; Eugenius A. Roche, St. Mary's Hospital.

HOSPITAL SUNDAY in Belfast has been permanently fixed for the last Sunday in each year.

A WOMAN named McEvoy died last week in the County Down, Ireland, at the advanced age of 106 years.

Deputy Surgeon-General Andrew A. Stoney, L.R.C.S.I., of Frankford, has been placed on the Commission of the Peace for King's County.

IN London last week 1504 deaths were registered, including 54 from measles, 120 from scarlet fever, 7 from diphtheria, 55 from whooping-cough, 25 from different forms of fever, and 14 from diarrhœa. No death from small-pox was recorded, making in all the nineteenth continuous week in which such a satisfactory announcement has been made. The deaths referred to diseases of the respiratory organs amounted to 374. The London Fever Hospital contained last Saturday 102 patients, including 85 cases of scarlet fever, and 12 of enteric fever.

RUMSEY TESTIMONIAL FUND.—Those desirous of subscribing to this fund are requested to do so at once, as the list will be closed before Christmas. Subscriptions may be forwarded to Dr. Buchanan, New Government Offices, Whitehall; to the Honorary Secretary; or to Messrs. Robarts, Lubbock, and Co., bankers. Cheques should be made payable to the "Rumsey Testimonial Fund" or bearer, and crossed "Robarts, Lubbock, and Co." Post-office Orders should be drawn on the Curzon-street Post-office, and forwarded to the Honorary Secretary.

THE SKIPTON GUARDIANS.—We are informed that only one candidate, and this one possessing but a single legal qualification, offered himself for election as medical officer to the Skipton Workhouse and Infirmary, at the salary of £35, which had been refused by the late medical officer under the circumstances mentioned in our issue of Nov. 13th. This candidate was elected, subject to the approval of the Local Government Board. We understand there are three or four doubly qualified practitioners in the town willing to take the appointment at a fair salary.

WHARFEDALE CONVALESCENT HOME, ILKLEY.—The committee of management of this institution has issued cards to the members of the medical profession announcing that the home will be opened for the reception of convalescents during the whole winter months, and that the arrangements for heating and ventilation are of such a nature as to ensure the most perfect warmth and comfort to the inmates. This determination has been arrived at through the strong wish of the founder, Mr. Charles Semon, to extend to others the benefits which can be obtained by richer people at kindred establishments.

The first meeting of the Surgical Society of Ireland was held at the College of Surgeons on the 26th ult., the opening address being given by Mr. E. Hamilton, president of the society.

At a meeting of the St. Pancras Vestry, held on Wednesday last, a letter was received from Dr. Thomas Stevenson, medical officer of health for the parish, tendering the resignation of his office, which he has held for a period of seven years, and stating as the chief cause of his doing so to be, "that while I am held responsible for the sanitary condition of the parish, I am denied that assistance in out-door inspection of houses, either visited with contagious diseases or habitually in an unsatisfactory condition, which I believe to be necessary. I feel that the severe condemnation which a house-to-house visitation of the poorer parts of the parish has received from a majority of the Sanitary Committee must of necessity hopelessly weaken my authority with the sanitary inspectors, and render nugatory my efforts to carry out the Sanitary Acts." The Vestry resolved to postpone the consideration of the letter until their next meeting, when some matters connected with the sanitary condition of the parish will also be considered.

Medical Appointments.

Abbott, C. E., M.R.C.S.E., has been appointed Surgeon to "The Atlas" Steam-ship, Cunard Line.

Bark, J., L.K.Q.C.P.I., has been appointed a House-Surgeon to the Royal Infirmary, Liverpool.

Barlow, T., M.D., M.R.C.P.L., has been selected as an Assistant-Physician to the Charing-cross Hospital, vice Poore, appointed an Assistant-Physician to University College Hospital.

Bartlet, G., M.R.C.S.E., has been appointed Medical Officer to the new Cottage Infirmary, Forgue, Aberdeenshire.

Bennett, J. H., M.D., M.R.C.S.E., has been reappointed Medical Officer of Health for the Redcar Urban Sanitary District: £15 per annum.

Boast, B. R., L.R.C.P.Ed., L.F.P. & S. Glas., has been appointed Medical Officer for the No. 3 District of the Henstead Union, Norfolk, vice Morgan, resigned.

Cremonini, J., M.R.C.S.E., has been appointed Resident Medical Superintendent of the Hoxton House Lunatic Asylum, vice Hunt, deceased.

Dale, W., M.D., M.R.C.S.E., L.M., has been appointed Honorary Physician to the West Norfolk and Lynn Hospital, vice Cossar, resigned.

Davison, F. V., M.B., has been appointed a House-Surgeon to the Royal Infirmary, Liverpool.

Goodwin, R. D., F.R.C.S.E., has been reappointed Medical Officer for the Mayfield District of the Ashbourne Union.

Gray, J. R., M.B., C.M., has been appointed Medical Officer for the Borrowby District of the Northallerton Union, Yorkshire, vice Buchanan, resigned.

Hall, J., L.F.P. & S. Glas., has been appointed Medical Officer of Health for the Leigh Urban Sanitary District.

Hayward, W. T., L.K.Q.C.P.I., M.R.C.S.E., has been appointed House-Surgeon to the Liverpool Infirmary for Children, vice A. James, M.B., resigned.

Jackson, W., L.R.C.P.Ed., has been appointed Medical Officer to the Skipton Union Workhouse, vice Birtwhistle, resigned.

Jumeaux, B., L.R.C.P.Ed., M.R.C.S.E., has been appointed House-Physician to the North Staffordshire Infirmary, Hartshill, vice Walter.

Lloyd, W., M.B., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the No. 1 District and the Workhouse of the Carmarthen Union, and Medical Officer of Health for the Carmarthen Sub-district of the Carmarthen Rural Sanitary District, vice D. Lloyd, M.R.C.S.E., deceased.

Mahon, C. J., L.R.C.S.I., L.K.Q.C.P.I., L.M., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Easkey Dispensary District of the Dromore West Union, Co. Sligo, and Medical Officer to the Workhouse, vice Scott, appointed to the Ballina Dispensary District.

Matthews, J. S., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer and Public Vaccinator for the Cloghan Dispensary District of the Stranorlar Union, vice Keys, appointed to the Castlefin Dispensary District of the Strabane Union.

Miles, G. E., M.R.C.S.E., has been appointed Assistant Medical Officer (temporarily) to the North Wales Counties Lunatic Asylum, Denbigh, vice Ellis, appointed Medical Officer to the Dinas Mawddwy Slate Quarries &c.

Milner, E., M.R.C.S.E., has been appointed a Surgeon to Out-patients of the Lock Hospital and Asylum, vice Shillitoe.

Pitt, C. W., M.R.C.S.E., has been reappointed Medical Officer and Public Vaccinator for the No. 1 District of the Malmesbury Union, Wilts.

Purcell, F. A., M.D., has been appointed a Physician to the Westminster General Dispensary, Gerrard-street.

Quinton, R. F., B.A., M.D., C.M., L.M., M.R.C.S.E., has been appointed Resident Medical Officer and Secretary to the Newark-on-Trent Hospital and Dispensary, vice Maybury, appointed a Medical Officer to the Colchester Union.

Shain, J. M., M.R.C.S.E., has been appointed a House-Surgeon to the Royal Infirmary, Liverpool.

Shillitoe, B., F.R.C.S.E., has been appointed a Surgeon to the Lock Hospital and Asylum, vice Lane, resigned.

Smith, S. J., M.D., L.R.C.S.E., has been appointed Medical Officer for the Etwall District of the Burton-on-Trent Union, vice Kitchener, resigned.

Twigge, T. N., M.R.C.S.E., has been reappointed Medical Officer for the Hartington District of the Ashbourne Union.

Walter, W., M.B., has been appointed House-Surgeon to the North Staffordshire Infirmary, Hartshill.

Willan, R. M., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the No. 4 District of the North Witchford Union, vice Wilson, resigned.

Winslow, Dr. L. S. F., has been appointed Lecturer on Psychological Medicine at the Charing-cross Hospital Medical School, vice Hunt, deceased.

Births, Marriages, and Deaths.

BIRTHS.

Atthill.—On the 25th ult., at St. Osyth, the wife of R. C. Atthill, L.R.C.P.Ed., of a son.

Gray.—On the 20th of Oct., at Cinnemara, Jorehaut, Assam, the wife of Edward Gray, M.B., C.M., of a son.

Lownds.—On the 23rd ult., at Egham-hill, the wife of T. M. Lownds, M.D., of a son.

Rice.—On the 28th ult., at Cadogan-place, the wife of M. W. Rice, M.D., of a daughter.

Sturton.—On the 23rd ult., the wife of H. W. S. Sturton, M.R.C.S.E., of Greenwich, of a daughter.

Taylor.—On the 25th ult., the wife of Dr. H. O. Taylor, of Castle-gate, Nottingham, of a daughter.

MARRIAGES.

Brebner—Simpson.—On the 28th of Oct., at Christ Church, Georgetown, Demerara, William Brebner, M.B., C.M., M.G.C.U.E., H.M.P.S., to Ellen Inniss, eldest and only surviving daughter of James B. Simpson, S.C.P. No Cards.

M'Kelvie—Gaedicke.—On the 22nd ult., at Berlin, civilly, and on the same day at the British Embassy, by the Rev. R. Bellson, English Chaplain, Robert M'Kelvie, M.D., of Cromer, Norfolk, to Mathilde, only daughter of the late Johann Daniel Gaedicke, Ph.D., Rector of Prenlau, Prussia.

Rigby—Thompson.—On the 23rd ult., at Barry-road Chapel, Peckham-rye, James Arthur Rigby, M.B., of Winckley-square, Preston, Lancashire, to Sarah Elizabeth Atherden (Lillie), eldest daughter of Joseph Thompson, Esq., of Manor House, Camberwell, Surrey.—No Cards.

DEATHS.

Brown.—On the 19th ult., at Burtholme, Cumberland, Robert Brown, F.R.C.S.Ed., aged 43.

Hardy.—On the 9th ult., at Warrington, Geo. Willmott Hardy, M.R.C.S.E., aged 74.

Leith.—On the 28th ult., at Etherton-lawn, near Tunbridge-wells, Dr. A. H. Leith, late Inspector-General of Hospitals, Bombay Medical Service.

Peterson.—On the 5th of Oct., at Bombay, Richard A. Peterson, M.D., aged 29.

Ready.—On the 26th ult., at Bootle, Michael Ready, M.R.C.S.E., aged 59.

Torrance.—On the 25th ult., at Dunchurch, David Torrance, M.D.

Tulloch.—On the 27th ult., at Pembridge-place, Bayswater, James S. Tulloch, M.D., aged 56.

Wales.—On the 31st of Oct., at Wimbotsham, Norfolk, Robt. J. Wales, L.S.A.L., aged 79.

Webster.—On the 24th ult., Wm. H. Bayley Webster, L.S.A.L., of Woodbridge-road, Ipswich, aged 83.

Wilson.—On the 16th ult., at Clachanton, Ayrshire, W. Wilson, L.F.P. & S. Glas., aged 60.

Notes, Short Comments, and Answers to Correspondents.

The Eucalyptus Globulus.

Some time ago the Army Sanitary Commission forwarded a memorandum to the Government of India regarding the alleged benefits which were expected to follow the cultivation of the Eucalyptus globulus in malarious districts. The reports that have since reached this country from India are such as finally to dispose of the question. It appears that the Government of India have been importing seeds of the tree for many years past at a considerable expense, but that the only places where it has been cultivated with success are Raneckhet, in the South-West Provinces, and the Neilgherries, in the Madras Presidency. All attempts to rear it in the plains, where its alleged anti-miasmatic qualities would be most appreciated, have proved failures. Mr. O'Connor observes: "It is a native of the cool temperate zone of the Australian continent and Tasmania, and its unsuitability to the tropical plains of this country seems now manifest." After enumerating the virtues currently attributed to the tree, he adds: "This catalogue of the virtues of the blue gum tree makes me think of the wonderful powers supposed 300 years ago to be possessed by that 'most holy herb,' tobacco." Clearly such statements want confirmation before they can be accepted. They bear, indeed, on their face the mark of exaggeration. In one of the papers in which an account of the properties of the tree is given it is stated that the British Government has largely grown it in India and on the West Coast of Africa, with astonishing results in the diminution of fever. Now, we know that in India no such results have been obtained, and on the West Coast of Africa attempts are only now being made to introduce the tree. Mr. Broughton, the Government quinologist, says that he has examined the bark and leaves of the Eucalyptus globulus, and that neither quinine, quinidine, chinchonidine, nor chinchonine is contained in the plant in any proportion.

A Subscriber should get the information from his medical attendant.

Animal Vaccination.

To the Editor of The Lancet.

Sir,—I was glad to see from the short report in your last impression that the subject of animal vaccination has been brought forward for discussion at the Medical Society of London. It is a question of the utmost importance at the present time. The growing distrust of vaccination and of vaccine lymph in this country, especially in the large towns, must be patent to all. It is being used by anti-vaccination agitators for their own purposes, and much mischief will be caused if we do not supplement our present vaccine supplies, especially in times of epidemic or vaccination panics, with a lymph which shall be above suspicion. I have shown elsewhere* at length that the Russians are before us in this matter; that in the Foundling Hospital at St. Petersburg, where most of the public vaccination is carried on, calf lymph has been used side by side with human lymph for the last five or six years. It is equally protective, and the failures in primary operations have, by care and perseverance, been reduced as low as two per cent. Surely what is possible in St. Petersburg is possible in England, and difficulties which have been surmounted by Germans in Russia should not be an impassable barrier to the countrymen of Jenner. Our Government should take up the question, and put it to the practical test of experiment and observation; for it would be worth much to have a lymph which should command public confidence, as well as admit of indefinite multiplication in the event of an epidemic. Difficulties might arise in regard to its carriage and storage; then use it fresh on the spot, and send reliable human lymph abroad. The use of calf lymph might not, it would not, do away with the many constitutional skin affections which follow the first irritation of the system, whatever it may be, whether teething or vaccination, in scrofulous subjects; but these could no longer be paraded as a terror to ignorant or nervous persons under the head of vaccino-syphilis.

The difficulties attending "animal vaccination" have been so strongly set forth by Dr. Seaton in the Report of the Medical Officer of the Privy Council for 1869 that there is danger lest its more encouraging features should be left out of sight. If Dr. Drysdale's paper serves to revive an interest in the subject, and to put the question more fairly before the profession, I think we may yet see calves attached to every large vaccination station, and the confidence of the public in the efficacy and safety of vaccination restored.

I am yours faithfully,

Cheltenham, Nov. 24th, 1875. Edward T. Wilson.

Audi Alteram Partem.

Dr. Metzquer lately read two papers before the Academy of Medicine of Paris, wherein he strives to prove the non-inoculability of tubercular matter. "I have had the honour," says the author, "of bringing before the Academy 31 experiments, which prove that, with non-tubercular matter, lesions may be produced identical with those excited by tubercular substance. 13 experiments prove that the nodules thus produced may become absorbed. These 44 experiments added to those of my first paper amount to 130 experiments, controlled by Messrs. Morel, Michel, and Feltz. I have shown that the nodules resulting from these inoculations may become absorbed, and really disappear in the majority of cases. I have proved that we can, at will, produce pulmonary or, speaking more generally, organic lesions, which have been erroneously looked upon as tubercular. To prove this, we need but inoculate solid matter of sufficient volume and easily reduced, either putrid or impregnated with putrid matter." The author then reviewed, critically, M. Villemin's experiments and the meaning he attaches to them. Finally, M. Metzquer said: "I maintain, after 130 experiments, that the nodules developed after the above-named inoculations have no analogy with tubercles, because—1st, they become absorbed in the majority of cases; 2nd, because they can be produced by the inoculation of different substances; 3rd, because, when experiments are undertaken with actual tubercular matter, no results are obtained except that matter be in an advanced stage of decomposition. The committee appointed to report upon these papers is exceptionally numerous, comprising Messrs. Villemin, Hérard, Colin, Henri Roger, T. Guérin, Hirtz, and Béhier. The first three are well known for their labours on this intricate question.

Mr. George Brown is thanked. The matter is unworthy of our notice.

Typhoid and Distemper.

To the Editor of The Lancet.

Sir,—I have much pleasure in answering the questions put by your correspondent, Mr. T. Paton, and am glad to find that the subject has been taken up by him as a veterinary surgeon.

Before communicating the evidence, I took every possible care to find out whether there could be any source other than that mentioned which could have produced the disease. I could find nothing, and therefore concluded that the dog alone was the source from whence the poison came. The house is perfectly familiar to me, and therefore I can speak of the sanitary arrangements with confidence. The drainage was thoroughly looked to only about a year ago. The cesspool is ventilated by a pipe passing up above the roof of the house, and the closet is in an entirely distinct part of the house to that occupied by the man. The family had only left the house about three weeks before the man was attacked, so there was no time for any alteration in the ordinary arrangements. The house was also occupied at the time by a housekeeper and several children; but no one else was attacked save his friend who visited him at the stable, and who was present when the stench was experienced. Immediately on discovering the nature of his disease, he was removed to his own room over the stable. No other cases have occurred in the neighbourhood, so the evidence still points to the dog as the only source from whence the poison was derived.

I am, Sir, yours faithfully,

Nov. 27th, 1875. H. H.

Medical Advertising.

The *Western Gazette* seems to be getting a favourite medium through which medical men who are averse to hiding their lights may notify their accomplishments to an admiring public. A registered practitioner lately sought by means of an advertisement in its pages to obtain at once a wife and a practice. In a more recent number of the paper, and under the heading of "Trade Announcements," we find the following advertisement:—

> "Dr. Brennand, having purchased the late Mrs. Culling's practice at West Lydford, feels justified in calling the attention of his patients to the fact, and in trusting to a continuance of their goodwill towards the same. Lydford House, West Lydford, Nov. 16th, 1875."

Sun Steam Engines.

M. Mouchot, Professor of Mathematics at Tours, brought lately before the Academy of Sciences of Paris an apparatus, by which the rays of the sun are concentrated, and heat the boiler of a steam engine. It consists of a conical reflector, a gas receptacle, and a boiler with blackened walls. The reflecting side of the mirror is turned towards the axis of the apparatus at an angle of 45°, which allows of a short and powerful concentration of heat. The rays come in contact with the boiler, and heat the same. It requires only eight minutes to bring five quarts of water to the boiling point. M. Mouchot has erected a large engine at Tours, which sets in motion an engine of one-horse power, quite regularly, from the rising of the sun to eight o'clock at night. The Academy has appointed a committee to report upon this invention. The names of the members are a guarantee that this learned body were much impressed by M. Mouchot's communication. They are, Messrs. Dumas, Bertrand, Faye, Hervé-Mangon, and Lesseps.

Dr. Sinclair, (Dublin.)—The subject shall be noticed next week.

Calabar Bean.

To the Editor of The Lancet.

Sir,—I should feel much obliged if you or any of your correspondents would tell me where Dr. Munro's cases of tic cured by Calabar bean, referred to by "M.D. Lond." in your impression of Nov. 20th, are to be found. I am anxious to try this same treatment to an obstinate case of neuralgic (periodic) headache, which has hitherto resisted all treatment, but before doing so wish to know more of the details.

Yours &c.,

December, 1875. Inquirens.

---

* St. George's Hospital Reports, vol. for 1875: Questions connected with Vaccination, by E. T. Wilson.

"Confectionery."

THE *Pall Mall Gazette* states that while cooks in this country have yet much to learn, confectioners are almost too skilful in their art, and occasionally manufacture delicacies out of the most horrible compounds. An example of what apparently may be done in this line is afforded by an application made the other day to the magistrate at the Manchester Police Court, by the superintendent of markets, for an order for the destruction of thirteen tubs of unwholesome butter which had been found on the premises of a wholesale confectioner, whose employés were making it up with flour into paste for what are termed "Eccles cakes." The city analyst, who had examined a sample of this mixture, said that "it had evidently been made up of the refuse of butter casks, and was altogether unfit for human food. It smelt very badly, and there were evidences of decomposition, owing to too large a proportion of fatty acids." A promise being given on behalf of the confectioner that the stuff should not be applied for the purpose of confectionery, but should be given up to a soap-boiler in the presence of an inspector, an order was made by the magistrate accordingly. A summons, it was stated, would be issued against the confectioner for having the "butter" in his possession.

Vomiting after the Administration of Morphia either per Orem or per Cutem.

DR. FRICKENHAUS has found that he can avoid this unpleasant symptom by using atropine in combination with the morphia. The solutions used are two per cent. of morphia, and one per cent. of atropine. The syringe has twenty-five cross lines filled with the morphia solution, and five with atropine. Of course cases may be met with where atropine is contraindicated, and it may also be objected that vomiting is hardly so frequent after the absorption of morphia as the author seems to think.

Mr. Thomas Bell must excuse us. It would be contrary to our custom to do so.

Camphor Poisoning.

To the Editor of THE LANCET.

SIR,—On Tuesday, Nov. 9th, I was hastily summoned at eight o'clock in the evening, eight miles into the country, to see Alice T——, aged five years, who by mistake had administered to her by her mother half an ounce of liniment of camphor in place of her mixture. The child was just recovering from an attack of scarlet fever, which she in common with her two brothers had contracted at the village school. The liniment in question was sent to anoint their bodies with, and had been put side by side with the mixture; hence the mistake. She at once complained of its taste, and burning of the mouth, throat, and stomach, and in ten minutes was sick, hot water being given to her to help its removal from the stomach, and on my arrival I saw two or three ounces of half-digested cake and fluid, strongly impregnated with camphor and oil particles, floating on its surface. During the vomiting, and in fifteen minutes (so I was told) after its administration, violent convulsions came on. When I saw her, three hours afterwards, she was black in the face; the body arched backwards; the teeth so firmly clenched that nothing could separate them; the eyes were wide open, pupils quite insensible to a strong light, but neither contracted nor dilated; the eyeballs were rapidly rolling from side to side, and there was great subsultus tendinum; the pulse was at times hardly to be felt, at others it was full and bounding; the breathing was gasping, with long intervals between each gasp, so that those watching often thought the child was dead; the surface of the body was warm, but not hot; I had no thermometer with me in my hurry. The treatment I adopted was to put the body into warm water, and apply to the face and head cold affusion, which very soon told upon the congested condition of the brain, and in an hour quite changed the colour of the skin to a light florid red; the pulse soon afterwards became more regular, but the convulsions did not quite disappear for seven hours. At one time I felt inclined to abstract some blood, but the irregular state of the pulse made me afraid she would die if I did so. As soon as she could swallow, three-grain doses of bromide of potassium were given, and repeated every two hours for four doses. After that she sank into a quiet sleep, and the next day, with the exception of a blistered condition of the tongue and a soreness at the stomach, which milk and fluid magnesia soon removed, she was quite well.

I remain, Sir, yours truly,
Bridgnorth, November, 1875. W. THURSFIELD, M.D.

A Tyrannical Paragraph in Austrian Law.

THE Government are introducing a new penal code into Austria, and both Houses are now discussing it. Paragraph 455 enacts that medical men, midwives, and apothecaries are liable to a fine of 100 florins or less for refusing or delaying their assistance in urgent cases. Petitions, signed by Medical Societies, are pouring into the Houses, complaining of this clause. It is evident that the application of it would be fraught with great difficulty, as it is not easy to define what an urgent case is. Besides, such a clause is an attack upon individual liberty, and, from the general bearing of the medical profession, perfectly uncalled for.

Chloral and its Effects.

To the Editor of THE LANCET.

SIR,—I should be obliged if, through the medium of your extensively circulated journal, I could obtain any information upon the following points:

1st. Whether the taking of chloral for several years, varying in amount from at first twenty to thirty grains up to of late 100 to 120 grains per diem, has been known to induce a condition of gastro-enteritis, characterised during life by frequent vomiting, great abdominal tenderness, pain, and constipation, with the passage of hardened fæces covered with opaque white mucus; and also after death by a highly injected state of the whole alimentary canal.

2nd. Also, whether such use of chloral has been known to produce some perversion of the moral feelings, with complete alteration of disposition and temper.

I am, Sir yours &c.,
December, 1875. F.R.C.P.

Charity and Humanity.

THE details of a curious will case were lately made public, which showed that the testatrix must have been actuated by an unusual consideration for dumb animals. After evincing her charitable feelings by bequeathing £2000 to the Cancer Hospital, and £500 each to St. Thomas's Hospital, Guy's Hospital, and the Earlswood Asylum for Idiots, the deceased lady directs that the cob mare and greyhound which were her late husband's are not to be sold. The mare is to be kept in a comfortable, warm, loose box, as it has been kept since her husband's death; is not to do any work either in or out of harness, and its back is not to be crossed by any member of her late husband's family, but is to be ridden by some person of light weight not more than four days in each week, and not more than one hour in each day, at a walking pace. A sum of £65 per annum is left for the support of the mare, and £5 per annum for the keep and care of the greyhound.

A Handsome Present.

IN Germany, France, and other countries, the recurrence of a Christian name in the almanack is celebrated by those who have been given that name at their baptism. Professor Dittel, of Vienna (who lately recommended the elastic ligature), rejoices in the Christian name of Leopold; and on the occasion of Leopold's day, quite lately, Baron Sina, one of his patients, sent him a beautifully worked casket, in which were twelve bank notes of 1000 florins each (about £1000). It is quite refreshing to record such acts of recognition on the part of patients towards their medical attendants.

Mr. J. Bunting is thanked. It is to be regretted that such circulars are issued by medical men.

Treatment of Ringworm.

To the Editor of THE LANCET.

SIR,—In your issue of Nov. 20th I observe a notice of the treatment of ringworm by means of a solution of boracic acid, as recommended by Surgeon-Major Watson. The plan I have adopted for many years is quite as simple, more easily applied, and requires no precautions as to the parts being prepared, or care taken that they should afterwards be allowed to dry, that the acid be not rubbed off. Practising among a class where the disease appears frequently, it has been my method to paint the parts affected with the ordinary tincture of iodine. The brush is brought not only over the spot, but a little beyond the margins. This I do on three successive days, and then order the patient to appear a week after the last application for inspection. Not in one case in a hundred have I to repeat the application. The advantages of this plan of treatment are:—1. It is easily and quickly applied. 2. It gives no pain. 3. It requires no dressing of any kind, and cannot be removed by accident. 4. The power of contagion is at once arrested. 5. It never fails to effect a cure. I am confident that whoever tries it will never think of using anything else.—Yours truly,
Kinghorn, Nov. 24th, 1875. JAS. WELSH, M.D.

Incontinence of Urine in Children.

DR. ULTZMANN thinks that the chief cause of incontinence of urine in children lies in the weak state of the sphincter, through which circumstance the detrusor acquires unusual power. He advocates the induced current. A small brass plug is to be placed in the rectum, and one of the poles connected with it, whilst the other may be placed over the symphysis pubis or the upper part of the thigh. The sittings should last from five to ten minutes. Dr. Ultzmann mentions nine cases, in some of which he met with success. The use of belladonna remains, however, of great importance in these cases.

M.R.C.S.—They can be prosecuted under the Apothecaries Act, and fined £20 if the magistrates perceive the legal offence.

Preservation of Morphia Solutions.

To the Editor of THE LANCET.

SIR,—I notice in the issue of THE LANCET of Oct. 30th an article to the effect that M. Vidal has succeeded in rendering solutions of morphia "less liable to spontaneous change" by the addition of a certain amount of chloral. Having been unfortunately obliged during the past five months to employ hypodermic injections of morphia upon myself, I have found, after over 700 trials, that a solution of any strength of the sulphate (I use sixteen grains to the ounce), if made with boiling water, with the addition of one minim of carbolic acid to each ounce of the solution, will not only preserve it clear and free from deposits of all kinds for an indefinite period, but may be employed without the slightest particle of soreness ever following the puncture of the hypodermic needle. This I have found to be the case, not only in my own individual instance, but in scores of others where I have used it.

Yours respectfully,
New York, November 15th, 1875. CHARLES A. BUDD, M.D.

Vivisection Extraordinary.

THE *Evening Echo* of the 17th ult., in recording the purport of a telegram from Berlin to a contemporary, makes a revelation which must, we think, prove a little startling to English readers. Certain rumours against the solvency of an eminent banking firm of Berlin and Stettin had, it appears, been set afloat. These having turned out to be groundless, their author was, we are told, summarily handed over to the "public prosecutor." This is indeed horrible. Are there no Huttons in Germany?

A. B.—Insanity is not a ground for divorce. Cruelty is a ground for a judicial separation, and when coupled with adultery forms ground for divorce. If the party complained of were shown to be lunatic during the whole time of the occurrence of the acts constituting legal cruelty, we think that it would be difficult to obtain a judicial separation; but if the party continued lunatic, confinement in an asylum would follow as a matter of course, and thus there would be separation, though not technically "judicial."

Microscopical Preparations.

We have received some specimens of histological preparations (normal and morbid), prepared by Arthur C. Cole and Son, of Everton, Liverpool. They are certainly admirable sections, and are beautifully mounted. To the teacher in search of typical specimens for the purposes of demonstration, such preparations as these must be invaluable. From the list of preparations also forwarded to us, we find many objects included which are not easily obtained, and the possession of which is essential to the accurate study of histology. The preparations are divided into three series of twenty-four specimens each: the one including injected specimens, the other normal, and the third pathological structures.

The late Professor Schuh.

The bust of this eminent surgeon was lately unveiled in the General Hospital of Vienna. The meeting was very numerous, and Dr. Salzer delivered an eloquent discourse, in which he dwelt on the skill and genius of Dr. Schuh as a surgeon, and on his qualities as a man and a teacher. The ceremony ended in quite a German manner, by a festive concerted piece, sung by the Choral Society of the Faculty.

Dr. Wardell will see that we have alluded to his excellent letters, which will do good in the newspapers. Of course they will have no effect on the anti-vaccinationists. It is their peculiarity that the more reason there is in an argument, the more are they insensible to its force. And we have given up reasoning with them. But such letters as those of our correspondent do great good in educating and informing the public.

Studens.—Consult our Students' Number.

Salivary Calculus.

Dr. Ultzmann mentioned before the Austrian Medical Society that he had a short time ago under his care a patient who presented a tumour of the cheek, which broke, and turned out to be the seat of a salivary calculus. The latter is as large as a hazel-nut, very hard, and composed of phosphate of lime. In general these stones are brittle, and composed of carbonate of lime.

We are compelled by the great pressure on our space this week to postpone the publication of several articles and communications.

Communications not noticed in the current number will receive attention in our issue of the ensuing week.

Communications, Letters, &c., have been received from—Sir H. Thompson; Mr. Savory, London; Dr. G. Johnson, London; Dr. Corfield, London; Prof. Lecorché, Paris; Mr. Wagstaffe, London; Dr. Sutherland, London; Mr. Marshall, Moulton; Mr. Bell, Uppingham; Mr. Gibson, Finsbury; Dr. Wilson, Cheltenham; Mrs. Baines, London; Mr. Mayne, London; Dr. White, London; Dr. Bon, Paris; Mr. Fleming, Holbrook; Dr. Taylor, Nottingham; Mr. J. G. Brown, London; Messrs. Sampson Low and Co., London; Dr. Nankivell, Chatham; Mr. Harris, London; Dr. Rogers, Ottawa; Messrs. Brown and Polson, London; Mr. Goyder, Bradford; Mr. Purvis, Greenwich; Dr. Sinclair, Dublin; Dr. D. Powell, London; Dr. Welsh, Kinghorn; Mr. Howse, London; Mr. Tindall, London; Dr. Leadon, London; Mr. T. Smith, London; Mr. Walker, Wakefield; Mr. Tegg, London; Mr. C. B. Murray, London; Mr. Whitaker, London; Dr. Weir, Nottingham; Mr. Sheer, Cardiff; Dr. Parkin, Brighton; Mr. Humphreys, London; Mr. Pick, London; Dr. A. Meadows, London; Dr. Charteris, London; Mr. J. Graham, Southsea; Dr. John Williams, London; Mr. Watkin; Mr. Bunting, Tottenham; Mr. Potts, Newcastle; Dr. Gilland, Wallingford; Mr. Elliott, London; Mr. W. D. Jones, London; Mr. Huss, Stirling; Dr. Fox, Winchester; Dr. Hayward, Liverpool; Mr. Pike, Gloucester; Dr. Davies, Ebbw Vale; Mr. Shenton, Edinburgh; Mr. Black, Chatham; Mr. Edwards, Bury St. Edmunds; Mr. B. Bevan, London; Mr. Patterson, Hailsham; Mr. Danvers, Uppingham; Dr. Budd, New York; Mr J. G. da Cunha, Port Louis; Dr. Humble, Corfe Castle; Mr. Harris; Mr. Colman; Mr. Ensor, Port Elizabeth; Mr. Morris, London; The Secretary of the Harveian Society; A Subscriber; M.R.C.S., Leeds; W. H. P.; The Editor of *Vanity Fair;* Surgeon; Studens; J. S.; R. W. P.; Delta, Chesterfield; The Registrar-General of Edinburgh; G. L.; Rusticus; M.D.; J. A.; L. D. Y.; C. F.; F.R.C.S., London; The Secretary of the Necropolis Company; A. K. C.; A. B., Norwich; A. K. C.; Peter Plain; The Editor of the *Veterinary Journal;* Iatros; Inquirens; H. H.; &c. &c.

Letters, *each with enclosure,* are also acknowledged from — Mr. Rigby, Preston; Mr. Wigg, Tunbridge; Mr. Whalley, Bradford; Mr. Thomas, Manchester; Mr. Vanes, Birmingham; Dr. Dickinson, Stalybridge; Rev. J. E. Clarke, Battersea; Mr. Walker, Corwen; Mr. J. Hebblethwaite, Bawtry; Mr. Evans, Seaford; Mr. Blasson, Edgware; Mr. Barnett, Weston-super-Mare; Dr. Kennedy, Fort William; Alpha, Durham; J. J. B.; M. L.; M.D.; H. M.; Medicus, Southport; L. L., Feltham; W. H.; Medicus, Welshpool; B. B.; L.R.C.P.; Douceur; K. K., Billingborough; Alpha, St. Helens; M. M.; Medicus, Newcastle; Alcazar; B. A.; P. W.; J. R.; T. E.; J. C. D., Petworth; M.D. Lond.; Medicus, Sheffield; T. M.; S. L. H., Islington; F. M., London; L. S. A., Padstow.

Newcastle Chronicle, Liverpool Post, Western Morning News, Birmingham Morning News, Welshman, Local Government Chronicle, Manchester Guardian, Record, Western Gazette, Weston-super-Mare Gazette, Surrey Advertiser, East London Observer, West Cumberland Times, Cork Constitution, Staffordshire Advertiser, Oldham Standard, Wrexham Advertiser, and *Keighley News* have been received.

Medical Diary for the ensuing Week.

Monday, Dec. 6.

Royal London Ophthalmic Hospital, Moorfields.—Operations, 10½ a.m. each day, and at the same hour.

Royal Westminster Ophthalmic Hospital.—Operations, 1½ p.m. each day, and at the same hour.

St. Mark's Hospital.—Operations, 9 a.m. and 2 p.m.

Metropolitan Free Hospital.—Operations, 2 p.m.

Medical Society of London.—8½ p.m. Mr. Maunder: Exhibition of Arm seven years after Excision of the Elbow-joint (living specimen).—Mr. Alfred Freer (of Stourbridge), "On a Case of Impalement, with Post-mortem results four and a half years afterwards."—Dr. Robt. Lee, "On different forms of Pessaries."

Tuesday, Dec. 7.

Guy's Hospital.—Operations, 1½ p.m., and on Friday at the same hour.

Westminster Hospital.—Operations, 2 p.m.

National Orthopædic Hospital.—Operations, 2 p.m.

West London Hospital.—Operations, 3 p.m.

Pathological Society of London.—8½ p.m. The following Specimens will be exhibited:—Molluscum Contagiosum; Dilatation of Bile-ducts; Aneurism of Aorta; Obliteration of Superior Cava; Ulceration of Duodenum extending into Vena Porta; Disease of Pulmonary and Tricuspid Valves; Hæmorrhagic Periostitis; Fatty Tumour of Cord; Congenital Deficiency of Common Bile-duct, and consequent Cirrhosis; Injury to Radius; Deformity from Rheumatic Gout; Cirrhosis of Liver in a Child; Recurrent Epithelioma in Chest and Toe after successful Excision of Tongue; Cancer of Heart and Supra-renal Capsules; Cancer of both Breasts and Ovary; Tumour of Clavicle; Aneurism of Aorta opening into Stomach; Arrest of Development of both Forearms; Report of Sequel to Dr. Walker's Case of Recurrent Sarcoma of Leg; Embolic Infarction in Heart Muscle; &c. &c.

Wednesday, Dec. 8.

Middlesex Hospital.—Operations, 1 p.m.

St. Mary's Hospital.—Operations, 1¼ p.m.

St. Bartholomew's Hospital.—Operations, 1½ p.m., and on Saturday at the same hour.

St. Thomas's Hospital.—Operations, 1½ p.m., and on Saturday at the same hour.

King's College Hospital.—Operations, 2 p.m., and on Saturday at 1½ p.m.

Great Northern Hospital.—Operations, 2 p.m.

University College Hospital.—Operations, 2 p.m., and on Saturday at the same hour.

London Hospital.—Operations, 2 p.m.

Samaritan Free Hospital for Women and Children.—Operations, 2½ p.m.

Epidemiological Society. — 8 p.m. Dr. John Wortabet (Physician to St. John's Hospital at Beyrout): "Sketch of the recent Cholera Epidemic in Syria."

Thursday, Dec. 9.

St. George's Hospital.—Operations, 1 p.m.

Royal Orthopædic Hospital.—Operations, 2 p.m.

Central London Ophthalmic Hospital.—Operations, 2 p.m., and on Friday at the same hour.

Harveian Society.—8 p.m. Harveian Lectures: Dr. Sibson, "On Bright's Disease and its Treatment, considered mainly in relation with Arterial Tension from Blood Contamination."

Friday, Dec. 10.

St. George's Hospital.—Ophthalmic Operations, 1¼ p.m.

Royal South London Ophthalmic Hospital.—Operations, 2 p.m.

Clinical Society of London.—8½ p.m. — Dr. Donkin, "On a Case of Diabetes treated with Skim-milk."—Mr. Haward, "On a Case of Lymphadenoma."—Dr. T. S. Dowse, "On a Case of Thrombosis of Cavernous Sinus; Sudden Loss of Vision; Hæmorrhage into Anterior Lobe."—Mr. Venning, "On a Case of Congenital Tumour."

Saturday, Dec. 11.

Royal Free Hospital.—Operations, 2 p.m.

Charing-cross Hospital.—Operations, 2 p.m.

NOTICE.

In consequence of The Lancet being frequently detained by the Post Office when posted for places abroad *more than eight days after* publication, subscribers and others are reminded that such copies can be forwarded only as book packets, and *prepaid* as such.

TERMS OF SUBSCRIPTION TO THE LANCET.

Post free to any part of the United Kingdom.

One Year	£1 12 6	Six Months	£0 16 3

To the Colonies and India.

One Year	£1 14 8

Post Office Orders in payment should be addressed to John Croft, The Lancet Office, 423, Strand, London, and made payable to him at the Post Office, Charing-cross.

TERMS FOR ADVERTISING IN THE LANCET.

For 7 lines and under	£0 4 6	For half a page	£2 12 0
For every additional line	0 0 6	For a page	5 0 0

The average number of words in each line is eleven.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday; those from the country must be accompanied by a remittance.

N.B.—All letters relating to Subscriptions or Advertisements should be addressed to the Publisher.

A Clinical Lecture
ON THE
PHYSICAL EXAMINATION OF THE URETHRA IN CASES OF STRICTURE.

Delivered at University College Hospital on November 18*th*, 1875.

By Sir HENRY THOMPSON,
SURGEON EXTRAORDINARY TO H.M. THE KING OF THE BELGIANS; EMERITUS PROFESSOR OF CLINICAL SURGERY IN UNIVERSITY COLLEGE HOSPITAL.

(*Reported by* Mr. G. Buckston Browne.)

Gentlemen,—To-day our subject is to be, stricture of the urethra. It naturally comes next in order; but I take it next also because it is generally supposed to be one of the most frequently occurring affections of the urinary organs. Not that it is so; on the contrary, it is certainly not present in a great majority of those who fancy they are the subjects of stricture. Many persons suffering from slight functional disturbance will come to consult you for "stricture." They do so because they find the stream a little twisted or forked, whilst nevertheless the urethra may be absolutely free from any organic change.

[After discussing the pathology and describing the symptoms of stricture, the lecturer proceeded to consider the mode of examining the urethra in order to ascertain the presence of stricture.]

For this purpose there are two separate modes to be followed, as there are two different objects to be attained, each of which is quite distinct from the other:—

There is, first, a simple examination of the urethra, to be used only for the purpose of verifying the presence or absence of any material deviation from the natural dilatability of the urethra;

And there is, secondly, a more minute and exact examination, in order to determine the precise condition of the urethra when it is already known, or there is reason to believe, that long-standing and perhaps considerable obstruction exists.

Now I need hardly say that the first examination is one which is applicable to the vast majority of cases; and that the second is necessary only in a few and exceptional cases. A very simple examination suffices to determine the question which so frequently comes before us—"Do certain not very considerable derangements of the urinary function in any particular patient arise from organic obstruction, and therefore require instrumental interference; or are they due to some other condition, for which instruments are not merely useless but would probably be injurious?"

Now, in reference to this subject, I find a tendency at the present day to employ instruments too readily, and instruments also which are liable to injure the urethra. This over-readiness to interfere with the urethra existed at the beginning of the present century. The mechanical school, as I shall take the liberty to term those who devise and largely employ more or less complex mechanical means for exploration, and for applying dilatation, cutting, or caustic to the unfortunate urethra, was then in the ascendant. I think I could amuse you for hours with the history of the surgical knick-knacks which have been produced by it. But our time is too valuable, and I will content myself with one illustration only of surgical practice in this country at the era I speak of. [Sir Henry Thompson then read some curious reported cases from the work of Sir E. Home, illustrating the extraordinary abuse of the bougie at that time.]

Following the period spoken of came the experience of mischief as its result, and a certain healthy reaction appears to have taken place. The practice of Sir Benjamin Brodie, who was subsequently so high an authority during his long career, was marked by caution and prudence, and his admirable teaching ensured a similar practice among others for some time. I may be allowed to say, perhaps, that my feeble voice has also been raised against the abuse of instruments from the first day that I ventured to pen a line on the subject, some two or three and twenty years ago. And now I perceive a growing disposition to return to the state of things I have referred to. I note an increased tendency to discover stricture, and especially to undertake a considerable amount of operative treatment for strictures of the slightest kind, and sometimes where, in my opinion, they do not exist. There seems now to be a school which has determined for itself a very high standard of patency in what we hear called the "urethral tube," and which is accordingly said to have, or, if it hasn't, that it ought to have, a calibre of so many parts, and very large parts, of an inch, or millimetres, as the case may be. Instruments of astounding magnitude are produced, and if one of them cannot be drawn, with an ease which contents the operator, through the whole of the urethra, the unlucky patient is pronounced to be the subject of stricture; and probably he is submitted to an operation by no means devoid of risk.

Now I don't know that this fashion has as yet been adopted here, but I do know that it exists elsewhere, and I raise my earnest protest against it. I feel it a matter of duty on my part to say what I think about treatment which I am perfectly certain neither you nor I would for a moment entertain the propriety of in our own proper persons; that is, if we entertain a due respect for that delicate passage which an intelligent acquaintance with it will ensure. Let us for a moment revert to the natural form which the urethra takes when it is distended by some fluid material, and observe how unlike it is to the coarse simile of a tube of known uniform diameter. We have already seen that its natural capability for dilatation varies greatly at different points: being much limited at the junction of the membranous and spongy portions; limited again, but less so, and somewhat irregularly, in the anterior part; and again at or near the meatus. Let me assure you also that there are few structures more delicate than the male urethra. Formed of an internal membrane of great tenuity, surrounded by elastic and muscular fibres, interpenetrated everywhere with ducts, fine blood-vessels, and nerves; the whole surrounded in front of the prostate with one of the most elaborate of vascular structures, known as erectile tissue; add to this the sensitiveness to pain of the internal membrane, equalling the conjunctiva in that quality, as anyone may learn for himself by passing the softest instrument he can find. Lastly, and more important still, it possesses another form of sensibility, of a much graver kind, which even the last-named membrane does not possess: I mean a strong tendency to arouse, in the entire nervous system, a state of excitement, evidenced by the striking phenomena of rigors and subsequent fever and prostration, when slight mechanical injury has been done to any portion of it. Now let this picture of the urethra as it is, never be absent from your mind's eye when you put an instrument into it, and both you and your patient will profit. When, therefore, a young man consults you for certain troubles relative to which you desire to learn whether urethral obstruction be a cause or not, do not be tempted for an instant to adopt so unnecessary a course (to say the least) as the introduction of very large instruments, or instruments with huge bulbs at the end of them. But simply take a flexible English gum-elastic bougie, well curved towards the point, with a blunt end (since a tapering point, of course, will not mark distinctly the site of stricture), not larger, as a rule, than No. 10 or 11 of our scale, and pass it very gently and slowly into the bladder. If it goes easily—above all, if it is withdrawn without being held, and slides out with perfect facility, take my word for it he has no stricture, and, *quoad* obstruction, wants no use of instruments whatever.

I dare say I shall be told by someone, that there may be a urethra through which No. 11 can be made to pass, yet which is, nevertheless, the subject of some degree of stricture which it is necessary to treat. Well, I do not deny the existence of that exceptional case. But such an example is very rare, and, further, no man who has the slightest delicacy of tactile sense in his fingers can fail to observe the difference between a No. 11 bougie sliding out with facility, and one which is grasped somewhat as it is withdrawn. This difference is always manifest in the two cases, and is, indeed, very notable. But supposing that the No. 11 stops at any point, and you have assured yourself that it is not one of the natural obstructions to the passage of an instrument through the urethra, of which I shall have to speak hereafter, you will try a smaller instrument of the same kind until you have arrived at one which does pass through and inwards into the bladder. But you may also test your observation by passing a soft tapering French bougie—11 or 12 English size,—and if it is a *natural* obstacle which at first checked your blunt-pointed bougie, the former instrument will probably slip through without trouble.

Now, with reference to these bulbous-pointed flexible explorers, nothing is more easy, especially with an unpractised hand, than to deceive oneself with respect to the existence of stricture by means of them. If not drawn out accurately in the axis of the passage, you may feel a check, and readily find what you believe to be a stricture in the most healthy urethra. And that is precisely what I am so anxious to guard you against; for, in the hands of designing persons, these instruments may be turned to most unworthy purpose. For men outside the ranks of our profession, or holding a questionable position on its outskirts, these instruments are the very thing. That is an additional reason why we should be careful not to encourage their unnecessary use. I have used small bulbous instruments in metal for the diagnosis of narrow and confirmed stricture, on which it is desirable to operate, for twenty years, but for slight stricture never; and I have protested against their use on the two grounds already named: first, that for such the instrument inflicts needless pain; secondly, that it is liable to deceive a young operator not too adroit or familiar with its use.

But now, in the second case—not that of the young man, but of the patient who has a confirmed stricture,—the diagnosis has probably to be conducted with more attention to detail. I proceed as follows, making what may be called a "survey" of the passage. I commence by passing the soft, blunt-ended English gum-elastic bougie as far as it will go; and when this stops, as it may do within an inch or less of the orifice, I make a note of the distance, and next find what will pass with tolerable ease through the obstruction met with. Very likely a No. 4 or 5 (similar instrument to the preceding) will do so, and it may then be carried further to seek another check, which is not unfrequently met with at about five inches from the orifice. Through this, after a trial or two, a very small gum catheter—say No. 1 or 2—may probably be passed into the bladder, drawing off some urine, and so assuring you of its position. I know then the patient has, at all events, a narrowing near the orifice and another at the distance named. I may verify this at once with a bulbous instrument if I choose; but as long as the anterior narrowing exists, it is as well to postpone more minute research until it is divided, as considerable narrowing at that part always requires to be. Such a one, indeed, is never advantageously treated by dilatation. This being done, the No. 11 blunt-ended bougie is passed, and we learn whether any contraction exists in the interval existing between it and the spot originally marked at five inches. If there is one, the stopping of the bougie will indicate its situation. But if the bougie passes easily to the point just named, the canal is sufficiently open, and we have arrived at what, in ninety-nine cases out of a hundred, is the only remaining stricture; for it is rare indeed, where a narrow stricture exists at that distance from the meatus, that any other will be found beyond. This has next to be dealt with, and, as we are speaking now of old and confirmed cases, there is little doubt that the best treatment will be internal urethrotomy. How to accomplish that most perfectly will be discussed in my lecture on that subject.

A word or two about the bulbous exploring instrument. It should, in my opinion, be of polished metal mounted on a slender metal rod or shaft. No other material slides so easily and smoothly through the urethra; and the necessity for it is, after all, not great, so that to employ one which produces much irritation, passes roughly, or distends unnecessarily, is to pay too high a price for the small amount of information it may convey. I am free to say that, although I used the metal bulbous instruments in the earlier part of my career, I can now, with more experience, attain all that is necessary without them. It is said that they enable you to ascertain the length of a stricture. In reference to this, let me tell you, first, that considerable narrowing almost never affects the urethra for any great distance. The passage is often partially implicated for half an inch behind and half an inch before the maximum point of narrowing—an important practical point in relation to operation; but the very narrow spot, which is what the exploring bulb indicates, is almost invariably short, within a quarter of an inch in extent. Secondly, you must take into consideration the fact that the mobility of the mucous lining of the urethra will deceive you if you are not aware of it. A very little pressure in front, on entering the stricture, or from behind, in withdrawing the exploring bulb, if it comes rather tightly through, changes the situation of the contracted portion considerably in relation to its distance from the external meatus.

I repeat, then, if you have to deal with a recent stricture, such a one as you naturally intend to treat by dilatation, the introduction of a large bulbous explorer is wholly useless, only produces unnecessary pain, and tends to excite inflammation.

But in view of any internal incisions for a confirmed or obstinate case, the important thing is simply to know where the narrowed points of the urethra are, and then it is not difficult to apply your cutting instrument properly to them.

But, before proceeding further, I wish to show you the proper mode of passing an instrument through the healthy urethra into the bladder, so as to avoid error arising from certain sources of difficulty which are *naturally* found there, and are often mistaken for stricture. Were the urethra a mere tube of uniform diameter, these would not exist. We shall observe in the particulars of its unlikeness to a simple tube, that such natural obstacles do exist, and have to be avoided.

ON CHLORIDE OF LEAD AS A DEODORISER AND DISINFECTANT.

BY R. H. GOOLDEN, M.D.

I WISH to call the attention of medical practitioners and especially of sanitary officers, through THE LANCET, to the value of chloride of lead as the most powerful and economical agent for eliminating sulphide of hydrogen from the atmosphere, as well as from all organic matter in a state of decomposition or putridity. There is nothing new in this fact. It is known to all chemists, but its application has been practically disregarded, owing to the popularity of other deodorisers, which having been made the subjects of patents are well advertised, and therefore generally adopted, and they certainly do answer the purpose with more or less completeness. Of these I may instance—Chloride of zinc (Burnett's), chloride of aluminium, hypochlorite of soda (Marvel Fluid), hypochlorate of potassa, hypochlorate of lime, permanganate of potassa (Condy's), permanganate of lime, peroxide of iron, peroxide of manganese, powdered charcoal, bog earth, and alluvial earth.

I need not enter into the *rationale* of the chemical action of these several ingredients, nor do I suggest the substitution of chloride of lead for the three last-named substances when it is proposed to convert organic matter into reproductive soil for farming or gardening purposes, but only in those cases where it is necessary to purify a fetid atmosphere, which has to be breathed by living people.

It has already been objected that zinc and manganese have been detected in plants grown in soil manured by stable-dung, which had been deodorised by Burnett's and Condy's fluids. I do not know how far the fact has been established, but even the suggestion is of such importance as to make us very careful in proposing the use of lead, unless it can be shown that lead is not in the same category. I think we may arrive at a strong inductive probability that it is not so; for the lead sulphide is quite insoluble except in strong nitric acid, in boiling hydrochloric acid, and in aqua regia (which is not the case with zinc or manganese); nor is lead sulphide absorbed in the human body when swallowed, but passes on by the bowel as harmless as powdered charcoal; and the affinity of lead for sulphur is so strong that lead sulphide cannot be resolved but at a very high temperature. Another safeguard lies in the very sparing solubility of lead chloride, and also in the very small quantity used in the deodorising process.

The chloride of lead and sulphide of hydrogen react with a simultaneous double affinity, producing an insoluble lead sulphide and hydrochloric acid. Lead is so readily acted upon by sulphur, that metallic lead and oxide of lead in paint, even when protected by the dried oil, is turned black in any atmosphere where sulphide of hydrogen exists. White paint in stables, waterclosets, and in artists' paintings, is soon turned black by it and spoilt.

To prepare it for use, take, for ordinary purposes, half a drachm of nitrate of lead, dissolve it in a pint or more of boiling water—(nitrate of lead is a soluble salt, and very cheap; it may be had in any quantity for about a shilling a pound, and should be much cheaper if bought in large quantities),—and dissolve two drachms of common salt (chloride of sodium) in a pail or bucket of water; pour the two solutions together, and allow the sediment to subside. The clear supernatant fluid will be a saturated solution of chloride of lead. A cloth dipped in this solution and hung up in a room will sweeten a fetid atmosphere instantaneously, or the solution thrown down a sink, watercloset, or drain, or over a heap of dung or other refuse, will produce a like result. Even the tarnishing of gold and silver plate may be prevented by a rag dipped in the solution being hung up in the room or window where it is exposed.

It will thus be seen that one great advantage of chloride of lead over all other deodorisers lies in its great cheapness. The cost of the quantity of nitrate of lead required for use may be estimated at a fraction of a farthing; it is easily carried about, or may be sent by post; it is a dry solid, is not caustic, nor will it discolour or blister the skin; it can be kept in paper or a pill-box, and therefore does not require a glass or other fragile bottle. The exact equivalent proportion of nitrate of lead and chloride of sodium would be 100 to 317 in weight. As it is necessary that the whole of the nitrate of lead should be converted into chloride, a slight excess of salt is desirable, but as chloride of sodium in the solution renders the chloride of lead even less soluble than in water, I have adopted the weights respectively as half a drachm to two drachms—sufficiently correct for all practical purposes. 331 grains of nitrate of lead converted into lead chloride are sufficient for 34 grains of sulphide of hydrogen. Now 36·38 grains of sulphide of hydrogen represents 100 cubic inches—a quantity quite ten times larger than under ordinary circumstances we are likely to have to deal with.

In sick rooms, hospitals, and crowded assemblies, we have to deal with the sulphide of hydrogen and ammonium, given off by the resolution of organic, especially albuminous matter in decay, or eliminated from the living body in fæces through the skin and with the breath; and it must be borne in mind that whenever great numbers of people are crowded together in rooms, as in balls, concerts, theatres, or schoolrooms, the human body gives off an amount of sulphide of hydrogen, and that it is this, and not the carbonic acid, that makes people exposed to such an atmosphere so depressed, and which, when highly concentrated, developes typhus poison. The quantity is indeed very slight compared with its power of offensiveness, as in the analogous case of various flowers whose scent is most powerful, producing a sensible effect upon the human organism, and yet the agreeable or offensive matter composing it is too small to be detected by any test except the olfactory sense; and hence it is that the small quantity of lead chloride contained in the solution is found practically to be quite sufficient to sweeten the most offensive room, and, in my experience, to deodorise any drain, watercloset, or sink.

A not less important direction, in which the use of the chloride of lead would prove of the utmost value to H.M. navy and the mercantile marine, is for the purification of bilge-water, and of the close, fetid atmosphere between decks in emigrant and passenger ships; easy of transport, occupying little room, and safely stowed away in paper or wooden boxes. The sea-water requiring no addition of salt, the solution is made without trouble, and need merely be thrown down into the bilge, where the ship's motion completes the process.

The following cases, which have occurred in my own practice, will illustrate its use and successful application:—

CASE 1.—A lady living in Chester-square, who was suffering from sciatica, consulted me many years ago, and my attention was called to a large tumour in the external part of the hip-joint. The tumour was soft and not very prominent, had been very gradually increasing, and with its increase the sciatic pains became more severe. Believing it to be a fatty tumour pressing on the sciatic nerve, I could only refer her to a surgeon for its removal. It was accordingly removed by Mr. Lane, and without any hæmorrhage at the time, and proved to be a large fatty tumour the size of a child's head. The sciatic pains ceased, and the patient appeared to be in a fair way to recover speedily the effect of the operation. About a week afterwards I was asked to meet Mr. Lane, and found that the cavity from which the tumour had been removed had been distended with blood in a state of decomposition, the patient suffering all the symptoms of blood-poison: small rapid pulse, black sordes coating the mouth, tongue, lips, and nose; wandering, muttering delirium; she would take no food. The room was most offensive, the smell penetrating to the passages and other rooms. Basins containing Condy's fluid, Burnett's fluid, and bog-earth were in various parts of the room, but exercised but little influence over the fetid emanation.

Wishing to try the effect of the lead chloride, we obtained, with great difficulty, a small quantity of nitrate of lead, and prepared the solution as above described. A towel dipped in it was hung up in the room, and *instantaneously* the smell disappeared. The wound was dressed, and over the wound some lint dipped in the solution was placed. The next day we met, and found our patient sitting up in bed, quite cheerful, with a clean tongue and good pulse, enjoying a mutton-chop and some port wine. The room was perfectly free from smell.

I have had many other opportunities of using this solution with equally satisfactory results, especially in paralytic cases, where, towards the end, the fetor of the breath and emanations from the skin are most offensive.

CASE 2.—Three years ago, after a very severe stormshower, the large drain at the back of the United University Club was burst by the flood, and opened to the atmosphere. A more distressing smell in its immediate neighbourhood could hardly be imagined. Carbolic acid was used in the Club, which substituted only one stink for another. I sent the steward for a pound of nitrate of lead, of which half an ounce was used. A towel wetted with the solution was hung up in each room, and the rest poured down the drains and into the sewer, and immediately all smell was gone. The neighbours, who were unaware of what was being done, expressed the greatest surprise at the sudden disappearance of the nuisance. Although the drain remained open for some days until it could be repaired, there was no more inconvenience felt from the smell.

CASE 3.—The wife of a horse-jobber in a very large way of business, apparently suffering from the poison of carbolic acid used to disinfect the stables where she lived, consulted me. She informed me that although the stables were well-drained and well-ventilated, the effluvium from the large number of horses and the accumulation of dung was so offensive that they had been induced to use carbolic acid, which, though painfully disagreeable, was not so offensive as the stable exhalations had been. It appeared also that since the use of carbolic acid they had lost seventeen horses, and that they could not help connecting their loss in some way with it. I recommended the immediate disuse of the carbolic acid, and in its place to try the nitrate of lead and salt. In a fortnight I saw her again in perfect health, and learnt that the stables had, from the first application, become freed from all disagreeable odour, and that the dung-pits into which some of the solution was regularly sprinkled were now sweet, to the great contentment of the horsekeepers and stablemen, with whom the removal of the dung has always been a subject of great difficulty.

CASE 4.—Some years ago, when visiting one of H.M. largest ships, I casually heard loud complaints of the nuisance caused by the bilge water. Through the courtesy of the officers, which was greater than their faith in any possible remedy, I was allowed to try the experiment of removing it, and, having procured half an ounce of nitrate of lead, it was dissolved in a bucket of boiling fresh water, and thrown down the bilge when the ship was rolling slightly. The effect was the instantaneous disappearance of all smell; a large white precipitate, which immediately afterwards became black, subsided to the bottom, and the bilge-water became perfectly clear. The cost was one halfpenny.

I have selected these few cases as leading types of the application and results of chloride of lead as a deodoriser and disinfectant, and only trust that they may be sufficient to lead my readers to continue the experiments in different directions, as I have hitherto found it to be the most simple, the most economical, and most successful of all the processes which have come under my notice.

Sussex-gardens, W.

CASE OF

GUNSHOT WOUND (BY DERRINGER PISTOL) OF CHEST AND ABDOMEN.

AUTOPSY AND REMARKS.

By RICHARD BARWELL, F.R.C.S.,
SURGEON TO CHARING-CROSS HOSPITAL.

A. B., aged twenty-one, shot himself with a Derringer pistol about 11 o'clock on the night of Nov. 14th, 1875. Dr. Reece saw him immediately after the injury, and directed his removal to Charing-cross Hospital. I was sent for, and arrived a little before 12 o'clock that night.

The young man had been sick instantly on receipt of the injury, and was in a state of considerable though not severe collapse. A round black wound, about the size of a sixpence, from which trickled down a drop or two of dark-coloured blood, lay over the cartilage of the left eighth rib about four inches from the sternum. No probe could be passed into this opening save for a few lines immediately below the skin, in a direction upwards and outwards. He complained of no pain except at the left acromion, where it was severe.

The Derringer is a very small toy-like weapon, about five inches and a half long, with a bore of four-tenths of an inch in diameter. It is a breech-loader. The cartridge consists of a copper cap, into the open end of which the conical bullet fits, the detonating powder being, of course, at the closed end. The fulminate is of very powerful quality, and a certain specified charge is put into each cartridge. No other propellent is, I am informed, ever added.

Finding, however, at the wound no passage inwards, I thought it well that a search should be made in the young gentleman's clothing, and elsewhere in his lodgings for the bullet, but nothing was found either there or among the undigested portions of food which he had vomited.

Nov. 15th.—This morning the collapse was deeper; he had been constantly thirsty, taking ice in lumps, brandy-and-water, and was also frequently vomiting. I again failed in passing any probe, and explained to my class that the bullet had in all probability passed through the cartilage, which had then closed again behind it like a trap-door. He complained of inability to pass urine, though the nurse said he was constantly doing so. There was no blood either in this excretion nor in the vomit. About 8 P.M. that evening he suddenly had a greater fit of vomiting, and the matter seemed to contain a little blood. He almost instantly died.

Post-mortem (Nov. 18th).—The body was much swollen, and the skin much discoloured, though there was less decomposition in deeper parts. The wound still refused to admit a probe (of course no force was used). On taking away the front of the chest the bruising and blackening was seen to occupy a greater space on the internal than on the external surface. For a long time no opening marking the track of the bullet could be found, although the pericardium, lungs, &c., were examined with the utmost care. At last a small slit was found in the diaphragm with no mark of bruising or extravasation around it. It was barely a third of an inch long, and only to be detected on very careful search. Of course this led into the abdomen, and on opening that cavity a little hole in the stomach was found, and on its posterior wall another; both these openings had a very narrow dark edging of extravasation. Removing the stomach, all trace of the bullet was lost; neither on the fat behind that organ nor elsewhere could any opening be found. The kidney was now removed, and in its upper and inner edge, just in front of the suprarenal capsule, a small crack or chasm was found, the extreme margin of which was blackened by extravasation. Behind the kidney, after careful search, a little split or rift was found in the fascia covering the psoas; it was not stained by effused blood. The probe when passed into this ran backward and a little upward, and on dividing the parts the bullet was found imbedded behind the muscle just above the transverse process of the second lumbar vertebra, its conical end directed almost directly upwards. On trying the bullet on the blackened spot on the eighth costal cartilage, it was found that by exercising rather considerable pressure it could be made to pass through a hole formed by three convergent rifts, which, instantly after the passage, snapped together again like the flaps of a valve, and left no hole nor perceptible trace of passage.

It appears to me that this case is of interest as exemplifying the fearful power of the little pistol—a thing which a man might conceal easily in his clinched fist, and which looks less formidable than many a child's toy; yet it propelled its shot all but through a full-sized man; and, as I saw, it will send a bullet nearly through an inch-thick oak board, shattering to a great distance the wood around its place of exit.

The next singular point is the very little injury the bullet did to the traversed tissues. The wounds in such vascular organs as the stomach and kidney had a dark margin of bruising less wide than the hem of a lady's handkerchief; but parts less richly supplied with blood showed merely minute slits where the bullet had passed, and among fat, as that round the kidney, no track could be found at all.

The symptom, a prominent one throughout, pain at the acromion, must, I think, be ascribed to wound of the diaphragm; the strangury to wound of the kidney.

George-street, Hanover-square.

REPORT ON THE

EFFECTS OF HIGH TEMPERATURES UPON WOOLLEN AND OTHER FABRICS.

By SURGEON-MAJOR F. DE CHAUMONT, M.D.,
CONJOINT PROFESSOR OF HYGIENE, ARMY MEDICAL SCHOOL.

(*Communicated by the* DIRECTOR-GENERAL OF THE MEDICAL DEPARTMENT OF THE ARMY.)

IN accordance with the Director-General's instructions of Oct. 18th, 1875, I have the honour to report as follows. The portions of fabrics selected were obtained from the store here, being condemned clothing &c., as under:—

1. Blanket—woollen, white.
2. Coverlets—woollen, coloured.
3. Hospital clothing—flannel, blue.
4. Sheeting—cotton.
5. Bed-slip—canvas.
6. Hospital lining—cotton.
7. Horsehair from mattress.

These were exposed as follows:—

Dry heat,	212° F.,	for	2	hours	
„	„	„	4	„	
„	„	„	6	„	
„	220° F.	„	2	„	
„	„	„	4	„	
„	„	„	6	„	
„	„	„	44	„	(8 + 15 + 15 + 6 hours) on successive days.
„	230° F.	„	8	„	Total, 13 hours on an iron plate on successive days.
„	„	„	5	„	
„	„	„	9	„	Total, 14 hrs. on a porcelain plate on successive days.
„	„	„	5	„	
„	250° F.	„	4	„	Total, 9 hours on successive days.
„	„	„	5	„	

The following results were observed on comparing the samples with the fabrics in their original condition:—

1. Blanket—

2	hours	at 212° F.,	no change.
4	„	„	„
6	„	„	a slightly perceptible yellowish colour.
2	„	220°	slightly tinged with yellow.
4	„	„	rather more deeply.
6	„	„	
44	„	„	a strong yellow tinge.
13	„	230°	on an iron plate, a marked yellow tinge.
14	„	„	on a porcelain plate, a very strong yellow tinge.
9	„	250°	on an iron plate, a strong yellow tinge.

The order in which the shades of colour showed themselves is as follows:—

Darkest,	14	hours,	230° F.,	on a porcelain plate.
„	44	„	220°	on an iron plate.
„	9	„	250°	„ „
„	13	„	230°	„ „
„	6	„	220°	„ „
„	4	„	„	„ „
„	2	„	220°	about equal.
„	6	„	212°	
„	4	„	„	hardly any change.
„	2	„	„	no change.

2. Coverlet.—Results very similar, but less easily seen on account of the colour of the fabric. In this case also the worst was the one exposed for 14 hours to 230° F. on a porcelain plate.
3. Hospital Clothing, Blue Flannel.—In this case exposure even for 6 hours at 212° F. did not seem to have any marked effect; but 2 hours at 220° distinctly changed the colour, and all the other temperatures produced more or less effect.
4. Sheeting, Cotton.—There was no perceptible change after 6 hours at 212° F., nor after the same time at 220°; 44 hours at 220° produced a distinct colour; as did also 13 hours at 230° (iron plate), moderately; 14 hours at 230° (porcelain plate), markedly; 9 hours at 250° (iron plate), markedly.
5. Bed-slip, Canvas—

6	hours	at 212° F.,	no change.
6	„	220°	slight change.
44	„	220°	marked brownish tinge.
13	„	230°	(on iron plate) marked brownish tinge.
14	„	230°	(on porcelain plate) not tried.
9	„	250°	(on iron plate) brownish tinge.

6. Hospital Clothing, Cotton Lining—

2	hours	at 212° F.,	no change.
4	„	212°	
6	„	„	slight change.
2	„	220°	a distinct discoloration in all, in varying degrees.
4	„	„	
6	„	„	
44	„	„	marked yellow tinge.
13	„	230°	(on an iron plate) moderate tinge.
14	„	„	(on porcelain plate) marked yellow tinge.

7. Horsehair.—No particular change was observable by exposure, except perhaps slight increase of brittleness.

The conclusions to be drawn from the above experiments are the following:—

1. Woollen articles are more liable to change by exposure to high temperatures than cotton or linen.
2. Woollen articles begin to lose colour after exposure for 6 hours to a dry heat of 212° F., or after 2 hours at 220° F. Higher temperature or longer exposure produces proportionally increased change.
3. Cotton or linen fabrics can be exposed for 6 hours at 212° F., or for 4 hours at 220° F., without perceptible change; 6 hours at 220° F. shows distinct change in some cases, and longer exposure or higher temperatures in all cases.

We may therefore conclude that *woollen* articles cannot be exposed to a dry heat of 212° F. longer than six hours without suffering injury, so far as colour goes, and that two hours at a temperature of 220° F. is sufficient to produce a similar result.

Cotton or linen articles may be exposed for six hours to a dry heat of 212° F. without apparent injury, but not for more than four hours at 220° F.

I beg to append a copy of a letter from Dr. Lake, one of the surgeons of the Southampton Infirmary, relative to the experience in that institution of a drying chamber heated by gas on Ransome's principle. It will be seen that the results correspond with the effects at high temperature recorded above.

"Our disinfecting stove was at work for about seven months regularly, and irregularly for about two months before that. During that time (seven months) all the patients had a mattress and blankets which had passed through the machine; the mattresses were, as a rule, in the chamber at least eight hours each time; the blankets at least two hours. Our plan was to begin, say Monday morning. After the chamber was heated (that is 240° or 250°) it was loaded with three mattresses; the temperature would drop to a little over 200°, and in about eight hours it would be again from 240° to 250°, when the mattresses were withdrawn. Thus in twenty-four hours we baked nine mattresses. The blankets were done after the mattresses were all finished; as many pairs as the machines could hold were introduced, but in two or three hours the temperature would rise to 240°, and another charge would be baked. In this way the whole week's work was got through in about fourdays. I have to-day asked both the matron and the porter who worked the machine what effect the process has had on the articles. They both consider it has damaged the materials. The matron states that the blankets are all damaged and have become yellow in appearance, but she is not prepared to say they give less warmth, and is unable to speak positively as to whether they will not last as long, but she thinks they will not do so. The mattresses, she says, have been very tender, the tick tearing very easily. The long-continued dry heat has, I think, a decided effect in damaging the intimate structure of the materials, certainly of the linen and cotton goods. After a long time even wood is utterly destroyed, and becomes brittle and breaks at the least strain.

"I fear the dry heat does slowly char fabrics; on the other hand, it seems most efficient. The matron reports a most marked effect on vermin—lice, bugs, and fleas; they have been conspicuously absent. I cannot report that we have had no cases of erysipelas, but they were very few, and our operations and wounds appear to have done more than usually well.

"I have the strongest impression that we have been using a most unnecessary heat. A temperature of 220° in a few minutes destroys utterly bugs, fleas, cockroaches, &c., and in less than an hour at least, at that temperature, they are quite brittle, and fall to pieces.

(Signed) "G. A. K. LAKE."

Southampton, Oct. 21st, 1875.

A SHORT ACCOUNT OF

EIGHT CASES OF ACUTE TUBERCULOSIS, WITH SPECIAL REFERENCE TO THE PRESENCE OF CASEOUS CENTRES OF INFECTION.

BY H. M. TUCKWELL, M.D., F.R.C.P.,
PHYSICIAN TO THE RADCLIFFE INFIRMARY, OXFORD.

EVER since the promulgation in this country of the doctrine that acute miliary tuberculosis depends on, and follows directly from, the presence of caseous centres in some part of the body, I have examined every case that has come under my observation with special reference to this important question. I propose to narrate the following cases in as short a form as possible, omitting for the most part any account of the symptoms, and merely giving a brief description of the post-mortem examinations.

CASE 1.—January, 1867. Girl, aged nineteen. Tubercular meningitis. The lungs, spleen, liver, and kidneys contained miliary tubercles. The peritoneum was unaffected. In the middle of the upper lobe of the right lung was an old vomica of the size of a walnut, with thick walls, smooth lining membrane, and cheesy contents.

Case 2.—February, 1868. Woman, aged twenty-three. Tubercular meningitis. A few miliary tubercles were scattered through the upper lobe of the right lung. The spleen, liver, and kidneys exhibited all the appearances usually present in cases of blood-poisoning, but contained no tubercles. The right Fallopian tube was dilated into a sac filled with cheesy pus. The left tube contained a smaller quantity of the same matter. There were signs of old peritonitis, with adhesions, in the pelvis, propagated from the diseased tubes; but there was no trace of tubercle in the peritoneum.

Case 3.—March, 1869. Man, aged twenty-six, admitted with angular curvature of the spine and paraplegia, but without any acute symptoms. After having been in the infirmary for two weeks, he became rather suddenly attacked with feverish symptoms and cough. His temperature rose steadily, his breathing became more and more distressed, his face dusky, and he died at the end of a week from the beginning of the acute symptoms. After death the brain was found to be unaffected. Both lungs were crowded with minute miliary tubercles; the upper lobe of the right lung was hepatised. The spleen was large, soft, and rotten. The liver was likewise large and swollen. Six of the dorsal vertebræ had their bodies carious, and separated from their periosteum by a thick layer of cheesy matter.

Case 4.—February, 1870. Boy, aged four. Tubercular meningitis. The lower lobes of both lungs were congested and thickly strewn with very fine miliary tubercles. No other organ was affected. One bronchial gland was enlarged and caseous. One small cheesy collection, of the size of a pea, surrounded by a thin capsule of investing fibrous tissue, was found in the lower lobe of the left lung.

Case 5.—August, 1871. Boy, aged fifteen. Tubercular meningitis. Both lungs were stuffed with miliary tubercles. The liver contained many tubercles on its surface and in its substance. The spleen was swollen and thickly strewn outside and inside with the same formations. One gland, of the size of a cobnut, with soft, putty-like contents, lay beneath the right sterno-clavicular articulation. The thickened capsule of the gland had ulcerated through at one spot and suffered the soft contents to escape into the surrounding tissue.

Case 6.—May, 1873. Man, aged twenty-one. Tubercular meningitis. Both lungs were stuffed with miliary tubercles. The liver was covered on its upper surface, and strewn throughout its substance, with the same tubercles. The spleen contained many of the same, as also the peritoneum covering the diaphragm, which was thickly beset with them. At the root of the right lung, and surrounding the right bronchus, was a cluster of large caseous glands, some of them softened and of the consistence of putty. Mesenteric glands enlarged and caseous.

Case 7.—April, 1874. Girl, aged fourteen. Tubercular meningitis. Miliary tubercles were sparsely scattered through both lungs. The peritoneum was sprinkled with a few similar tubercles. One small cheesy nodule, of the size of a pea, was imbedded in the lower lobe of the left lung, and surrounded by a thin capsule, which had at one part ulcerated through. In the immediate neighbourhood of this spot the tubercles were much more thickly scattered than in any other part of the lung.

Case 8.—September, 1875. Girl, aged ten. Tubercular meningitis. The lungs were stuffed with miliary tubercles. A few of the same were scattered over the peritoneum. At the root of the lungs, surrounding the bronchi, was a mass of enlarged and cheesy bronchial glands. The mesenteric and lumbar glands were much increased in size, many of them caseous.

The evidence afforded by these cases seems to be, on the whole, corroborative of the German doctrine above mentioned. In all of them caseous stuff, in greater or less quantity, was found. In Cases 4 and 7 the apparent insignificance of the supposed centres of infection deserves notice. It may well be asked, Is it possible that a spot in the lungs no larger than a pea could bring about so deadly a train of symptoms, and, in the course of two or three weeks, sow the body with miliary tubercles? To this it may be answered, that the fact that the tubercles were thickly clustered round the spot in question, and seemed to radiate from it in all directions, is a fair reason for believing that this little degenerate mass may really have been the focus of infection; and this belief is further strengthened by a reference to the inoculation experiments of Villemin, Simon, Sanderson, and others, which will show how minute a speck of cheesy matter, introduced into the body of the animal experimented on, is sufficient to determine a widespread dissemination of miliary growths.

A second difficulty that presents itself, and seems to militate against the acceptance of this doctrine, is how to account for the fact that caseous glands, withered remains of former abscesses, and other collections of the kind, are often met with in post-mortem examinations without any accompaniment of miliary tubercle. It will be found, however, in all these degenerate remains of former inflammations, that the cheesy matter is surrounded by a capsule of greater or less thickness. The slowness of progress in the inflammation, which is presupposed by the very presence of caseous changes, gives rise to gradual thickening of the investing capsule in glands, of the surrounding fibrous tissue in old vomicæ or "residual abscesses"; and thus constructs a boundary-wall of protection which shall prevent future devastating excursions of this dangerous degenerate matter into the surrounding tissues or into the blood. It seems probable that, were it not for this mode of protective isolation by the natural encapsuling of degenerate products, many who are now walking about in apparently good health would have become long ago the victims of acute miliary tuberculosis. And here it may be allowable to turn aside for an instant to the subject of pyæmia and pyæmic centres, which, from this point of view alone, not to speak of other manifold resemblances, offer in their relations a striking likeness to tubercle and tubercular centres. It is well known to surgeons that abscesses in certain parts of the body are very likely to be followed by pyæmia. A very small and seemingly insignificant purulent centre, provided that it hold a certain relation to the surrounding tissues, may sow the body with multiple abscesses, and destroy life in a time which can be reckoned by days rather than weeks. In illustration of this reference need only be made to the acute periosteal abscesses of young persons. I have put up in the Oxford Museum a preparation of secondary abscess in the walls of the heart, from a boy who, after an illness of ten days, died of pyæmia, with secondary deposits in many of his internal organs, consequent on an abscess, not larger than a walnut, between his clavicle and its periosteum. I have also seen the same thing happen on two other occasions, where the small primary abscess lay between the tibia and its periosteum. On the other hand, large collections of pus, which may be even putrid, can form in the body under other conditions and with other surroundings, and not give rise to pyæmia. What are these conditions? This question has lately been handled by Mr. Savory in the columns of The Lancet of Nov. 13th, 1875, p. 692. He submits that the explanation of this difficulty is to be found in the fact that the abscesses which do not infect "are bounded everywhere by a layer of new structure, which is, or has the character of, granulation tissue, and that this limitary membrane, when sound and unbroken, resists the passage of fluids through its substance into the blood." He alludes also to Billroth's experiments, which show that granulation tissue, when healthy, has this power of resistance. Now, may we not see here a parallelism between the investing granulations of an abscess and the investing fibrous tissue of a caseous centre? Let but an "accidental breach" in the investing abscess-wall occur, and the body is pyæmic. Let there but be in the cheesy centre a breach through the surrounding fibrous capsule to form a way into the circulation for the degenerate matter, and the body is smitten with acute tuberculosis. In Cases 4 and 7 it will be noticed that the investing capsule had been apparently opened by ulceration, and the soft contents suffered to escape into the surrounding tissue. Dr. Hermann Weber* has recorded some striking cases of the same kind.

Lastly, it may be pointed out that only occasionally can a direct spreading by contiguity from the caseous centre to the neighbouring tissues, and from thence a gradual infection of more distant parts or organs, be demonstrated. The tubercles may often be found at a distance from the centre, as if the infection were rather by way of the blood than by direct extension through the tissues.

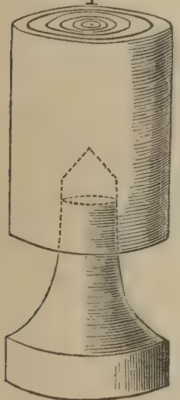
A SIMPLE FORM OF FREEZING SECTION MACHINE.

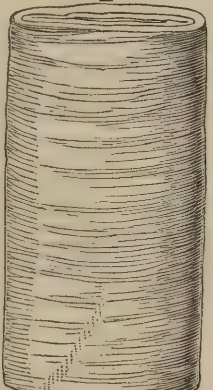
BY URBAN PRITCHARD, M.D., F.R.C.S.,
PATHOLOGICAL REGISTRAR TO KING'S COLLEGE, LONDON, AND SURGEON TO THE ROYAL EAR DISPENSARY, SOHO.

THE difficulty of cutting thin sections of soft tissues has for many years past been acknowledged by histologists, and several methods have from time to time been suggested for solving the vexatious problem. Hardening the tissue by means of certain reagents, such as alcohol, chromic acid, &c., is the plan that is usually followed, and it is one, too, that answers well under ordinary circumstances. Frequently, however, it is desirable to cut the tissue in its fresh state, especially in the case of pathological structures, and for this reason the idea of freezing the tissue was projected. In the *Journal of Anatomy and Physiology* for May, 1871, Professor Rutherford described his excellent machine for this purpose, which is a modification of Stirling's microtome, with the addition of a surrounding ice-box. This form of machine is very useful, as I have found from considerable experience; but it necessarily requires much time and care in its use, and it was with a view to render the instrument simpler and more rapid in its action that I designed the little apparatus I will now describe.

1



2



It consists of two pieces—(1) a metallic cylinder fitted with a wooden handle; (2) a cap of thick felt.

(1) The metallic cylinder, which is solid throughout, should be made of copper on account of its conductivity, but gun metal, or even brass, will answer the purpose sufficiently well. Its exact size or shape is not of very much consequence, so long as it is large enough and convenient to handle. The following dimensions I recommend: diameter of metal cylinder 1⅜ inch, length 1¾ inch; the diameter of the end of the wooden handle (*b*) should also be 1⅜ inch; the plug end should taper gradually, and the hole in the metal be a deep one, so that the plug may be pushed further in when the metal contracts on cooling. Both the wooden and metallic ends are made flat, so that the instrument can stand on either extremity; on the metal surface are a series of half a dozen concentric shallow grooves.

(2) Is simply a cap of thick felt, such as is used for boilers being preferable, made so as to fit somewhat loosely over the machine (1).

Mode of using the machine.—Plunge (1) with metallic face downwards into a mixture of finely pounded ice and salt; after remaining therein for three or four minutes, take it out and wipe with a clean cloth. The instrument has now been cooled down far below the freezing point, and on placing upon the metal plate a piece of soft tissue, this immediately freezes to the machine. The cap (2) must now be placed over the metal, but not allowed to touch the tissue, which will then freeze throughout in a very short space of time, varying according to the size of the tissue from a few seconds to one or two minutes. Now reverse the cap so as to leave the metallic top free, and, holding the whole in the left hand, cut the sections with the right by means of a sharp razor which has been kept cool in ice-and-water. Occasionally, the tissue may slip on the metal; when this is the case, remove the preparation, moisten it with gum-water, and replace it, when it will be found to adhere with much greater firmness. This slipping, however, very rarely occurs with perfectly fresh tissues, the grooves on the metallic surface tending to prevent it. The tissue will remain frozen quite long enough to make several score of sections, but should a thawing action set in, it may be covered with thin gutta-percha, and the machine again plunged into the ice-and-salt.

The advantages of this little machine are, first of all, its simplicity; and, secondly, the rapidity with which tissues may be frozen by its means. To illustrate the quickness of its action, it is only necessary to drop a little water on the cooled metal to convert it immediately into ice. Lastly, the apparatus may be made by any instrument maker or metal turner for a few shillings.

Mr. Baker, of Holborn, and Mr. Swift, of University-street, are manufacturing these machines.

To those who are specially interested in the subject, I may mention that I propose showing the little instrument in action at the next meeting of the Medical Microscopical Society (Dec. 17th).

Guildford-street, Russell-square, W.C.

CASE OF FIBROID TUMOUR OF THE MASSETER MUSCLE.

BY KELBURNE KING, F.R.C.S.,
SURGEON TO THE HULL GENERAL INFIRMARY.

JOHN S——, aged thirty-two, was admitted into the Hull Infirmary on March 2nd, 1872, under the following circumstances. For two years he had noticed a hard swelling in the region of the left temple, which extended down to the back of the left cheek. It was of slow growth, but as it grew he became unable to open his mouth, and, after the end of six months, he could separate his jaws only sufficiently to admit the thickness of a match. Latterly he had lost even this slight power of separation. His jaws were immovably fixed, and he lived entirely by suction through interstices between the teeth. He followed his employment as a labourer in a ship-building yard as long as he could, but of late he became so weak through insufficient nourishment that he was compelled to leave his work and apply for relief.

On admission, a hard lump, about the size of a damson plum, was felt in the centre of the masseter muscle, and another less distinct in the temporal, about an inch above the zygoma. The tumours had the feeling of enlarged, violently contracted muscular masses. Thinking it possible that the disease might depend on hypertrophy and permanent contraction of the muscles, I immediately administered chloroform, and, that failing to produce any relaxation, I divided the masseter subcutaneously. A certain amount of relief was afforded, and the jaws could be separated so far as to admit the patient's finger.

This mitigation was not permanent. On March 30th the closure was again complete. Chloroform was administered, and subcutaneous section of both muscles was performed. Some temporary relief followed, but the advantage gained was lost by degrees.

It was now evident that some other proceeding must be resorted to for his relief. The swelling was now most marked in the temporal region, and I resolved to remove the zygomatic process, so as to relieve the tension of the masseter, and get access to the insertion of the temporal muscle.

Accordingly on May 1st I performed the following operation:—An incision was made over the zygomatic arch, from the prominence of the cheek bone to almost half an inch in front of the ear. Another incision was made at right angles to this, extending about an inch above and below it. The flaps were dissected back, the masseter divided from the lower and the temporal from the upper margin of the zygoma. The bone forceps were then applied to the anterior and posterior extremities of the arch, which was removed. The insertion of the temporal muscles into the coronoid process was thus brought into view. The process was nipped through with bone forceps, and the muscle lifted up and dissected out. A hard dense structure was found in the centre of the muscle, which was freely removed. Four vessels required ligature.

Great improvement followed this operation, though I was myself disappointed with the results. The hard mass in the masseter continued, but the man could eat meat cut small, and was himself satisfied with his condition, and left the house on June 1st.

He again presented himself on June 24th with his jaws firmly closed, in the same condition as when he first applied for assistance. The temporal region presented a flattened appearance from the removal of the muscle, but the hard substance was still felt in the belly of the masseter.

I determined to remove the masseter, and, if necessary, to disarticulate the bone and remove the whole ascending ramus. On the 26th June, chloroform having been administered, an incision was made from the angle of the jaw to the cicatrix of the old incision over the zygoma, which was again laid open. The flaps having been dissected back, the masseter muscle was dissected away from the bone and removed. The ramus was thus laid bare, but it was found irremovably fixed by numerous strong fibrous connexions with the neighbouring bones. It seemed as if every part of the temporal muscle which had escaped excision had been converted into fibrous or tendinous structure, which held the bone firmly in its place. Under these circumstances I determined to remove the bone, which was done by dividing it from the last molar tooth to the angle by means of saw and bone forceps, then freeing it from its connexions, and disarticulating its head from the glenoid cavity. The wound healed favourably. He could open the mouth well, and left the hospital in a few weeks able to masticate freely on the right side.

I saw the man lately, and he continues quite well.

Mr. Plaxton, the pathologist to the infirmary, made several microscopic examinations of the tumour and muscular substance, and the following is his report:—"The tumour on section showed that it was not distinctly marked off from the healthy muscle, the greater part of masseter and temporal muscles being converted more or less perfectly into a hard creaking mass. The microscopic examination showed that the muscles were in process of conversion into fibrous tissue; isolated muscular fibres were to be seen between thick bundles of wavy fibrous tissue."

The muscular substance is not often the seat of disease. Though recurring fibroid is said to be frequently reproduced, it does not often originate in it. Mr. Tatum mentions a case in which he removed two recurring fibroids from the masseter and temporal muscles, but there was no train of symptoms such as I have related; neither was there anything of a recurring nature in these tumours, there having been no previously existing tumour, as in Mr. Tatum's case.*

I consider, therefore, that this is a specimen of a very rare form of disease, and in the absence of any precedent to guide us as to treatment, I believe that nothing short of the extreme measure finally taken would have afforded relief. The man masticates only with the right side of his mouth, but he can open the jaws perfectly, and is now healthy and in good condition.

SUCCESSFUL CASE OF TRACHEOTOMY IN A CHILD TWO YEARS OLD.

NEW FORM OF TRACHEOTOMY TUBE.

By W. E. Paley, M.R.C.S., &c.,

HOUSE-SURGEON TO THE EVELINA HOSPITAL FOR SICK CHILDREN.

The following case seems worthy of record, partly on account of the tender age of the patient (two years), and because a new form of tracheotomy tube was used, which appears likely to be beneficial in many cases.

Ada L—— was admitted October 5th, 1875, into the Evelina Hospital, under the care of Dr. F. Taylor. A week previously she was taken suddenly ill with sore-throat and feverishness. There had been, however, no difficulty of breathing until the day before admission.

When admitted there was evidence of considerable laryngeal obstruction. The respiration was noisy, and there was marked laryngeal cough, with sucking-in of the intercostal spaces. Air could be heard entering both lungs fairly well, and the chest was resonant throughout. No diphtheritic membrane could be seen, nor did the urine contain albumen.

The patient was at once placed in a steam tent, but towards evening the symptoms became more urgent, and it was decided to perform tracheotomy. This I accordingly did, without chloroform, introducing an ordinary silver tube. Great relief of all symptoms was immediately afforded, nor was there any recurrence of the dyspnœa.

The details of the progress of the case for the few days immediately succeeding the operation present nothing worthy of special note. Subsequently several attempts were made to dispense with the tube, but without success.

At the expiration of a fortnight the silver tube was changed for a new kind of tube suggested by Mr. Morrant Baker, the details of which were carried out under my direction by Mr. Millikin, of St. Thomas's-street. The tube is single, of ordinary tracheotomy shape, and constructed entirely of flexible india-rubber. It could be inserted easily without a pilot, and did not require to be changed more than once in every two days. As far as could be judged from a single case, it was introduced with less pain, was more comfortable to the patient, and caused far less irritation than a metal one; and with some slight modifications now being made it will, probably, prove a useful instrument.

I may add that the tube was worn for one month, during ten days of which the child was running about the ward; and we were able to discontinue its use altogether on Nov. 22nd, since which date the patient has left the hospital well.

So far the tube is not proposed by Mr. Baker as a substitute for a metal one at the time of operation, but to obviate the many well-known disadvantages the latter has when required to be worn for more than a few days. But it is not unlikely that, in many cases, the elastic tube might be used with advantage throughout, as there would probably be little or no difficulty in its introduction, at the time of operation, with the help of a proper pilot or forceps.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum, tum proprias collectas habere, et inter se comparare.—Morgagni *De Sed. et Caus. Morb.*, lib. iv. Prooemium.

ST. THOMAS'S HOSPITAL.

ANEURISMAL VARIX OF LEFT COMMON ILIAC VEIN; COMPRESSION OF AORTA; GANGRENE OF INTESTINE.

(Under the care of Mr. Simon.)

The previous history of the following interesting case, for which we are indebted to Mr. S. Osborn, surgical registrar, was published in The Lancet of March 6th, 1875.

Thomas K——, aged thirty-eight, a driver in the Royal Engineers, was admitted into Albert ward on Feb. 16th, suffering from aneurism within the abdomen. On the 3rd of March, after the patient's bowels had been thoroughly cleared out by castor oil, compression of the abdominal aorta by tourniquet was commenced at 10 A.M., preceded by the subcutaneous injection of half a grain of morphia at 9.30, which was repeated at 10 A.M. Mr. Simon not being satisfied with the instrument, which failed to control completely the pulsation without digital assistance, it was discontinued at 11 A.M., but recommenced at 11.30, the same instrument being supplemented by a cord attached to the side of the bed, another injection of morphia being given at 11.30 A.M. After the application of the tourniquet the heart-murmur became more marked, and the pulse increased in frequency, probably partially due to excitement; profuse perspiration of body and flushing of face, the legs presenting a blue, mottled appearance.—12 P.M.: Restless, and complaining of very great pain. Temperature 95°. Subcutaneous injection of half a grain of morphia.—2.30 P.M.: Pain less severe, and patient quiet. Temperature 95.6°. Extremities warm; compression not invariably complete, blood occasionally passing, but stopped by an additional turn of the screw.—5.20 P.M.: Hiccough came on and lasted about a quarter of an hour, during which time pulsation was felt in the aneurism. This pulsation continued until the screw of the tourniquet was brought into a vertical position by means of another cord attached to the bed; pulsation then ceased in the tumour and in both femoral vessels.—6.30 P.M.: Feet cold; left leg feels less tense than before; penis rather turgid.—10.30 P.M.: Compression remains effectual; dozes a good deal; hands rather cold; pulse 104.—11.10 P.M.: Passed five ounces of very offensive, clear, brownish urine, non-albuminous.—11.25 P.M.: Complains of a good deal of pain; screw loosened half a turn without any pulsation becoming perceptible; hands feel warmer. Subcutaneous injection of half a grain of morphia.

---

* For Mr. Tatum's case, see Holmes's System of Surgery, vol. iii., pp. 639, 640.

March 4th.—1.15 A.M.: Temperature 99°; pulse 102; not complaining of much uneasiness.—3 A.M.: Tourniquet removed; slight pulsation perceptible in tumour and right femoral; both legs warm; patient restless; subcutaneous injection of half a grain of morphia administered; ulcerated surface on left leg looks unhealthy, and greenish in colour; an oval, red, and tender patch above umbilicus, corresponding to where pressure of tourniquet was applied, to be relieved by warm fomentations. During the whole time of compression no nourishment was taken, with exception of a teaspoonful of milk occasionally. Measurement of left thigh, 27 inches.—9 A.M.: Sleeping, looks much worn; pulsation in tumour decidedly diminished.

5th.—Was troubled all day yesterday with hiccough, which still continues with increased frequency; patient much depressed and exhausted; was sick at intervals from 11.30 P.M. until 2.30 A.M., bringing up about a pint and a half of black fluid; bowels acted twice. Morning temperature 98.4°; evening temperature 99°; pulse 120; some tenderness of abdomen, but only at point of pressure; ulcer on leg is now black in colour; slight pulsation in right femoral.

6th.—Morning temperature 98°; pulse 106; no more vomiting; hiccough still continues; appears to be doing well, but is still much depressed. Took four ounces of brandy and some champagne in the afternoon.

7th.—Morning temperature 98.8°; evening temperature 99.8°; vomited about four pints of black offensive fluid during the night, and again three pints in the afternoon.

8th.—Wife anxious to remove him, which was with great difficulty prevented; patient feels better; no pulsation in aneurism perceptible; hiccough still continues, also vomiting of black offensive fluid. Morning temperature 98°; evening temperature 100.6°.

9th.—Much worse this morning. Morning temperature 100.8°; sickness still continues; is gradually sinking. He died at 12.55 P.M.

Post-mortem.—The abdominal walls corresponding to the point of pressure were about double their ordinary thickness, due to inflammatory infiltration. The great omentum was freely adherent to the anterior abdominal wall, but presented no sign of inflammation. The peritoneal cavity contained between three and four ounces of turbid fluid. Intestines distended, especially the upper part of the small intestine; on their external surface there was scarcely any trace of inflammation, but they were glued together, especially towards the flanks, by a very thin layer of inflammatory lymph; but here and there were seen pearly spots varying in size from that of a sixpence to that of a pea, corresponding to the parts where the necrosis had removed the whole thickness of the intestine, with the exception of the serous surface, and would eventually have perforated through into the peritoneum. Mucous membrane of stomach congested and dotted with minute punctiform injections, so also the upper part of the small intestine, the injection becoming more marked as the intestine proceeded onwards, assuming at length a deep purplish-red colour. About two feet below the pylorus, on the edge of the valvulæ conniventes, were minute yellowish flakes resembling croupous exudations, this condition gradually increasing until the greater part of the ileum presented a uniform wash-leather-like slough, the mucous membrane being of an ochrous colour, relieved by the velvety red edges of the valvulæ conniventes. Springing from the point of bifurcation of the abdominal aorta was seen an aneurismal sac about the size of a hen's egg, lined by a thin layer of fibrin. The left common iliac vein, which was greatly dilated, opened directly into the sac, and had no communication with the inferior vena cava. The superior mesenteric artery was completely obliterated for a considerable length, where, together with the mesentery, it was converted into an inseparable brawny mass.

ST. BARTHOLOMEW'S HOSPITAL, CHATHAM.

FIVE CASES OF LIGATURE OF THE FEMORAL ARTERY WITH ANTISEPTIC CATGUT.

(Under the care of Mr. Nankivell.)

Case 1.—C. V——, aged twenty-six, a cabman, was admitted on April 17th, 1871, suffering from an aneurism of the left popliteal artery, of the size of a small orange. Patient stated that he had noticed the swelling for about three weeks.

On admission, compression was applied, and continued daily at intervals for as long a time as the man could bear it till May 22nd, when, no result having been produced upon the aneurism, the femoral artery was tied with antiseptic catgut in the usual situation. The operation was performed strictly in accordance with the rules laid down by Mr. Lister. Lac plaster was used as the dressing. On June 12th the incision was found to be soundly healed. There had been an entire absence of suppuration throughout.

Case 2.—E. R——, aged thirty-three, having previously undergone amputation of his left leg for diffused popliteal aneurism, was admitted on November 22nd, 1871, for a right femoral aneurism situated in Hunter's canal. On November 27th the artery was ligatured in Scarpa's space, carbolised catgut being used for the ligature, and the usual antiseptic dressings applied. The wound did not unite by first intention, but the pus never became putrefactive. The wound was found to be healed on December 28th.

He subsequently died at home of an aneurism of the aorta.

Case 3.—J. S——, a mineral-water maker, aged twenty-eight years, was brought to the hospital on June 20th, 1873, suffering from an aneurism of the left femoral artery, situated at the lower part of Hunter's canal. The man stated that twelve days prior to admission he noticed a swelling in the affected part. He could not account for the tumour by any fall or blow. The affected limb measured over the aneurism an inch and a quarter more than its fellow. Carte's tourniquet was applied.

July 4th.—The sac of the aneurism had become very painful. On measuring the limb it was found to have increased two inches since admission. In the afternoon deligation of the artery was performed, carbolised catgut and gauze dressings being employed.

25th.—Since the operation there had been a trifling discharge of aseptic purulent fluid from the lower part of the wound, which, on removal of the dressing, was found to be quite healed.

He left the hospital on August 6th.

Case 4.—C. V——, the cab-driver mentioned in Case 1, reapplied for admission on April 14th, 1874, suffering from a popliteal aneurism of the right leg, which had existed for the previous eleven months, but had got much worse since Christmas.

On April 24th the artery was ligatured, carbolised catgut and gauze being the materials used. The dressings were changed daily, owing to the amount of discharge, which was, on April 28th, distinctly fetid. There was also an erythematous blush of the leg and thigh.

May 3rd.—Suppuration more profuse. The gauze was discontinued and poultices applied.

21st.—An abscess had formed in the groin, which was opened. The wound in the thigh granulated rapidly, and was quite healed on June 17th, on which day the patient left the hospital.

Case 5.—W. P——, a waterman, thirty-nine years of age, became an in-patient on November 11th, 1874, suffering from a popliteal aneurism of the right leg. Six months ago the man was admitted, but he then refused any operative procedure. Having become worse, he was readmitted on the above date, and the femoral artery was tied with carbolised catgut on Nov. 13th. Dry lint was used as the dressing till Nov. 16th, when poultices were applied.

Dec. 23rd. — Patient allowed to get up. Wound now merely a small superficial ulcer.

He left the hospital on Jan. 13th, 1875.

Remarks.—Cases 1 and 2 have already appeared in The Lancet of August 26th, 1871, and February 10th, 1872. These facts deserve mention lest some surgeon on a future occasion, in collecting statistics, should count them twice over. The above five cases illustrate fairly what the antiseptic catgut can do. They are not brought forward as instances of the success or failure of the antiseptic treatment, but simply to show the results of catgut ligature on arteries deligated in continuity. In none of these patients was there the slightest sign of secondary hæmorrhage, nor was any portion of the ligature seen in the dressings. The wound was healed in twenty-one, thirty-one, twenty-one, fifty-four, and forty days respectively. In attempting to compare the period of cure of cases treated by catgut, on the one hand, and silk or hemp, on the other, it is difficult to arrive at satisfactory conclusions, because of the melting away of the ligature in the one instance and of the separation of the thread in the other. Mr. Nankivell does not think that the presence of the catgut prevents primary adhesion of the deeper parts of the incision. At all events, he was not troubled by any sinuses, as has been stated to have occurred in some cases in the practice of other surgeons.

HÔPITAL TEMPORAIRE, PARIS.

CASE OF DIABETES.

(Under the care of Prof. Lecorché.)

The following case of diabetes, presenting some interesting points, occurred in the practice of Prof. Lecorché.

P. R——, aged twenty-four, an oil purifier, was admitted into the hospital on the 24th Aug., 1875, with diabetes. His mother and sisters are all living and enjoying good health; his father died of rheumatism. Had only been once ill himself, and that with an attack of pneumonia. No history of syphilis or of intemperance.

About a year ago the patient seems to have experienced great moral sufferings, owing to some family affairs and the death of a young person whom he was about to marry. These sufferings seem to have made a most painful impression upon him.

His health began to fail three months before his entrance into the hospital. He had a constant feeling of fatigue and a sensation of weakness in the extremities. He got visibly thinner, but remarked that his appetite had increased and that he was troubled with constant thirst and his tongue was continually dry. Shortly after he began to feel a need of frequently voiding his urine, and was also troubled with some dyspepsia, burning behind the sternum, and vomiting.

On admission the patient was greatly emaciated; weight 114 pounds; complained of sharp pains in the calves, dry burning feeling of the throat and tongue; the latter was of a dark red hue and mottled with white streaks denuded of epithelium in certain spots; appetite good, but has sour eructations after copious meals. Pulse 60, strong and regular; heart-sounds normal, as also the proportion of red globules in his blood. For the last two months he had had no penile erections. His sight became confused when he read for more than five minutes, and he sometimes saw red circles; at other times everything appeared white to him; there was paralysis of accommodation. His temperature during the first part of his stay in the hospital varied from 36° to 36·8° C.

The urine was pale-citron colour, slightly acid, and contained 40 grammes of sugar and 4 grammes of urea to the litre. For the first week the average quantity of urine was 3½ litres in the day, and 2½ at night. At this period the patient had a slight attack of bronchitis, which was not followed by any bad consequences. The appetite, which had diminished under the influence of certain gastric disorders, was now again good, the patient eating eight portions a day, and 500 grammes of meat. He drank about 6 litres of liquid a day.

September 25th.—The patient had diarrhœa, and from this date the urine averaged 4 litres a day—sugar 35 grammes, urea 2·5 grammes per litre. He was put under treatment, consisting of opium pills, gluten bread, Vichy, and an azotised diet. He showed some signs of an amelioration in his condition.

28th.—Passed 8 litres of urine. Proportion of red globules diminished.

October 2nd.—Passed 10 litres of urine. Was ordered 4 grammes of jaborandi. Sweated profusely, and expectorated 3·50 grammes of alkaline saliva.

5th, 6th, and 7th.—Passed 10 litres of urine. Profuse sweating. Salivation.

8th.—Patient left the hospital at his own request.

November 7th.—Patient entered the hospital again. He had tried to work again, but was obliged to cease on account of his strength failing. He perceived a swelling situated on the lower part of the outer side of the leg. This swelling had come on without any traumatism or pain. Little by little the temperature rose, the tumour increased in size, and the skin became distended.

8th.—Fluctuation was easily felt in the tumour. Temperature 37·2° Cent. Average of urine 8 litres in 24 hours; specific gravity 1031; sugar 76 grammes, urea 5·6 grammes per litre; red globules 3,500,000 per cubic millimetre. Evening temperature 38° Cent.

10th.—Abscess opened, gave vent to 300 grammes of laudable pus. Chloral dressing.

11th to 16th.—Average of urine was 9·3 litres per diem, and the temperature lowered down to 36·6°. Abscess presenting a favourable appearance.

17th.—Urine 12 litres; sugar 100 grammes, urea 7 grammes per litre.

This increase in the proportion of sugar was due to the weakness consequent on the inflammation.

Remarks.—Prof. Lecorché indicated the following points of interest in the case:—1. The etiology of this case would tend to confirm the opinion entertained by MM. Claude Bernard, Seegen, Bouchardat, and Pavy, as to the influence of nervous causes in determining the disease. (Experiments of Claude Bernard on Spinal Cord, 4th vent.) 2. The enormous quantity of sugar, 1200 grammes a day, and the fact of the urea being always in proportion to the quantity of sugar, as stated by MM. Pettenkofer, Vogt, and Lecorché, who admit an augmentation in the quantity of urea in cases of diabetes; polyuria being in proportion with quantity of sugar. 3. The formation of an abscess, which was opened without the supervention of any gangrene, which is stated to be the general result in cases of this kind by certain authors. This complication verified the statement that the temperature rises in diabetes under the influence of an intercurrent inflammation. Under the influence of this inflammation the quantity of sugar was reduced to 300 grammes, which augmented to 1200 grammes as soon as the appetite returned, notwithstanding the treatment he was put under. Prof. Lecorché terminated his remarks by saying that he regarded all treatment in advanced stages of the disease as almost useless, and considered that in these stages the proportion of sugar in the night urine might equal, and even exceed, that of the day.

Bequests, &c., to Medical Charities.—Mr. Wynn Ellis bequeathed £15,000 to the Hospital for Sick Children, Great Ormond-street (£10,000 to the general fund and £5000 to the building fund), and £2000 each to the Royal Westminster Ophthalmic Hospital, the Royal Infirmary for Women and Children (Waterloo Bridge-road), the Royal London Ophthalmic Hospital, and the Seaside Convalescent Home, Seaford. Mrs. Elizabeth Balls, of Streatham, bequeathed £2000 Consols to the Cancer Hospital, and £500 Consols each to the Earlswood Asylum for Idiots, St. Thomas's Hospital, and Guy's Hospital.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

The ordinary meeting of this Society was held on the 7th inst., Mr. Geo. Pollock, President, in the chair. Many cases of great interest and importance in a clinical as well as a pathological point of view were brought forward. Among them may be indicated an example of obliteration of the superior vena cava (probably congenital), shown by Dr. Habershon; a specimen of pulmonary and tricuspid disease, by Dr. Morison; and one of cirrhosis of the liver in a child, by Dr. Griffiths, of Swansea. The latter case led to some interesting facts as to alcoholism in children.

During the evening the following gentlemen were elected members of the Society:—A. E. J. Barker, H. W. Page, M.B., G. J. Malcolm Smith, M.B.

Mr. **Jonathan Hutchinson** made some remarks upon three cases of Molluscum Contagiosum, which were peculiar in the widespread distribution of the eruption. He exhibited drawings of the eruption from a man aged fifty, in whom, at first sight, the affection might have been mistaken for lichen, so small were the spots, which were distributed all over the trunk and limbs. They were largest and most characteristic on the back, where their origin in sebaceous glands could be well seen, and the contents readily extruded by pressure. In the two other cases the eruption was similarly diffused, but the spots were more characteristic. Mr. Hutchinson remarked upon the somewhat rare occurrence of the affection in the adult, and on the copious eruption in these cases, which also had a clinical value, in that in one of them it had been for some time treated as a syphilide. In reply to the President, he stated that there was no history of contagion to be obtained in the case.—Mr. **Waren Tay** said that some three years ago a man aged about forty presented himself at the Hospital for Diseases of the Skin covered by molluscous spots, except on the face and scalp. No history of contagion could be obtained. Examined microscopically they showed the usual features of the affection.—The **President** thought it would be of interest if Mr. Hutchinson would state what treatment he pursued. — Mr. **Hutchinson** said that in the first case the spots were too numerous to be treated in the ordinary way — viz., slitting up each nodule with the scissors. In one case, however, he had so cut out nearly two hundred of the spots. — Dr. **Coupland** referred to the recent researches of C. Boeck and Lukomsky, who appeared to have arrived independently at the same conclusion as to the histological nature of the molluscous tumour, which they regard as having but little to do with the sebaceous glands, but to depend rather upon a peculiar modification of the upper layers of the rete Malpighii. The change consists in the formation of the so-called "molluscous bodies" within the epidermic cells, which some authors have mistaken for spores, and others for fat or altered sebaceous products. — Mr. **Hutchinson** said that the sebaceous origin of the molluscous nodule was undoubted and most easy of demonstration, the inspissated secretion of the gland being readily squeezed out of each nodule.

Mr. **Morgan** exhibited a specimen of Stricture of the Hepatic Duct with Cystic Dilatation of its Terminal Radicles. It was obtained from a patient fifty-two years of age, who was admitted into St. George's Hospital with jaundice, pain in hypochondrium, and headache. His symptoms dated back four months, when he was attacked with diarrhœa. The liver enlarged under observation, and two tumours could be felt on its surface. There was found to be extreme fatty degeneration of the heart; the liver was much enlarged, smooth, and presented several cysts projecting on the surface, which proved to be formed by dilatation of the bile-ducts. The gall-bladder was distended, and a stricture of the common bile-duct just below its origin was found. The duct was adherent at the point of stricture to a perforating ulcer of the duodenum.

Dr. **Legg** showed a specimen of Congenital Stricture of the Hepatic Duct, with consequent cirrhosis, obtained from an infant who had lived to the age of five months, having been jaundiced from birth. There was no bleeding from the navel when the funis separated. The liver and spleen enlarged under observation. After death the hepatic and portal vessels were found to be natural. The cystic and hepatic ducts opened into a cyst the size of a marble, between which and the duodenum passed a membranous band. Followed towards the liver, the right hepatic duct was first much dilated and then greatly thickened, so that its branches within the liver could not be pursued. The left duct was thickened throughout, and almost impervious. The liver was granular and markedly cirrhotic. The spleen was very large. Dr. Legg stated that there were only eleven such cases on record, two being recorded in the Path. Trans., one by Dr. Wilks and the other by Dr. Nunneley. In Dr. Nunneley's case the infant lived seven months. He thought that the cirrhosis of the liver was secondary to the dilatation of the bile-ducts, because of the rarity of cirrhosis in infants, the limitation of the thickening to the walls of the ducts, and the fact that ligature of the duct in animals led to similar interstitial increase of connective tissue. There was no evidence of syphilis in the present case. It appeared probable that in many cases of umbilical hæmorrhage there was a similar congenital obliteration of the duct, but post-mortem records of such cases are rare. Dr. Legg thought the occurrence of umbilical hæmorrhage could be explained by connective tissue growth in the hilus of the liver constricting the portal vein, and thus tending to keep the umbilical vein open, the blood flowing in the direction of least resistance. In many cases of umbilical hæmorrhage there was bleeding from other parts of the portal tract.

Dr. **Fred. Robinson** showed a specimen of Aneurism of the Ascending Aorta. The aneurism was of the size of a walnut, and was seated just above the central aortic cusp, pressing on the pulmonary vein. The pericardium contained sanguinolent fluid, but there was no communication between it and the aneurism. The specimen was obtained from a soldier, forty-three years of age, who had contracted syphilis thirteen years previously, but who at the time of the onset of the aortic symptoms showed no evidence of the syphilitic taint. He suffered from precordial pain, and on examination a soft systolic bruit was heard over the aortic valves. The existence of aneurism was not suspected during life. Death took place suddenly. Dr. Robinson remarked upon the question of aneurism in relation to syphilis, and stated that, in his opinion, syphilis, intemperance, and pressure on the chest were the three main causes of aneurism, but he did not think that syphilis played so great a part as had been recently propounded. He thought also that the effect of pressure was mainly to produce disease of the heart.

Dr. **Habershon** exhibited a remarkable specimen of Occlusion of the Superior Vena Cava in a man thirty-seven years of age. He had been a coalheaver, and had remained well till seven years before his death, when swelling of the face and great congestion of the face and upper extremities came on, with great distension of the superficial abdominal veins. A diagnosis of intra-thoracic tumour was made, and the patient left the hospital partially relieved, having taken iodide of potassium. He returned, however, at the end of a year, and finally sank from dropsical effusion into the abdomen. Fomentations only afforded partial relief. After death it was found that the superior vena cava was obliterated; its position in the right auricle was marked by white puckering of the endocardium; the innominate veins ended in a cul-de-sac, and large communicating veins passed in front of the pericardium into the mammary veins, also into the smaller and greater azygos veins, by which the blood was carried downwards into the inferior cava, and thus reached the heart. There was much fibroid thickening around the aorta and in the position of the superior cava; the pulmonary valves were imperfect, there being two valves and the rudiments of a third placed on a somewhat lower level; there was some chronic peritonitis, but no disease of the abdominal viscera. Dr. Habershon thought the occlusion to be congenital, in support of which he adduced the malformation of the pulmonary valve and the absence of syphilitic disease or tumour. If the obliteration of the cava had been from without, there would have been more evidence of an opening into the auricle.—Dr. D. Powell asked if there was any history of cyanosis in early life. The cicatricial-like appearance of the part where the vena cava should enter seemed to favour the view as to its congenital origin.—Dr. Habershon said that the man appeared in good health up to thirty years of age, and followed his arduous occupation without any shortness of breath or other symptoms of venous obstruction.—Dr. Curnow asked how the blood found its way from the left side of the body into the auricle.—Dr. Habershon replied, chiefly by the left innominate, the intercostals, and the small azygos vein, as well as by a large vein passing over the pericardium to join the mammary vein. The upper part of the azygos major was obliterated.

Dr. Habershon also exhibited a case of fatal Hæmatemesis, in which the hæmorrhage came from a chronic ulcer in the first part of the duodenum. The vena porta was perforated; a sloughing cavity extended to the fissure of the liver. There was inflammatory change along the portal vein, and several abscesses in the liver. The gall-duct was partially destroyed.—In answer to Dr. Legg, who inquired in what way the bile escaped, and why there was no jaundice, Dr. Habershon said that the duct was not obliterated, although partially destroyed. The bile passed into the duodenum through the sloughing cavity.

Dr. Alex. Morison showed a specimen of Disease of the Tricuspid and Pulmonary Valves obtained from a youth twenty years of age. He had had scarlet fever when five or six years old, and was known to have heart disease when eight years of age. There was a strong family history of rheumatism, cardiac disease, and phthisis. The patient had never had rheumatism, and had enjoyed fair health till about eighteen years of age. There was a systolic bruit close to the left edge of the sternum, near the xiphoid, not traceable round the left chest; while over the third left rib and second space, close to the sternum, there was a hard, grating, double murmur, not propagated into the larger systemic arteries, but towards the left shoulder. There was evidence of great enlargement of the heart, regurgitation into the jugulars, epigastric pulsation, &c. There was engorgement of the lung and albuminuria. A few days before death some œdema of the face and scalp appeared. The necropsy revealed obstruction and regurgitation through the pulmonary valves, which were much altered and distorted by warty growths. The tricuspid valves were similarly diseased. The right cavities were hypertrophied and dilated. From the physical signs, the pulmonary lesion was easily detected, but it was thought that the apex systolic murmur might be mitral, though the failure to trace it round the left chest seemed to negative this view. During life the patient had some attacks of purpura, probably due to the venous engorgement and resulting capillary stasis.—Dr. Greenfield thought it possible that the lesion was not one of ordinary endocarditis, and on his suggestion the specimen was referred to the Committee on Morbid Growths.

Dr. Griffiths exhibited a specimen of Cirrhosis of the Liver obtained from a female child ten years of age. The parents were healthy; there had been seven children, of whom three had died in infancy, but there was not the slightest evidence of syphilis. The present child had scarlet fever at the age of three, and had suffered from infantile paralysis. Early in 1870 she had an attack of vomiting, followed later by jaundice, with enlargement of the liver; no ascites, no anasarca. The cause of this enlargement was obscure, there being no lymphatic affection, no tubercular or pleuritic history. The jaundice lasted about two years, and the child improved in health, but last year ascites supervened. The liver was now small, the spleen very large. Some jaundice again occurred, and the ascites increased. Paracentesis was twice performed, but the child sank. The liver weighed fifteen ounces; it was hard and tough, and partly adhered to diaphragm. It presented all the characters of cirrhosis.—Dr. Murchison said the case was of great interest as bearing upon diagnosis. He confessed to have been somewhat sceptical as to the occurrence of cirrhosis of the liver in children, but only quite lately he had met with a case of cirrhosis of the liver in a child nine years of age; and here, as probably in other cases that have been recorded, there was undoubted evidence of spirit-drinking. The child's father was a publican, and the child used to crave for drink, and had every opportunity of satisfying its craving. It certainly was highly probable that cirrhosis might be so caused in early life, considering the functions of the liver at that time. Dr. Griffiths's patient seems to have been delicate, and might possibly have taken wine medicinally, but in sufficient quantity to induce cirrhosis.—Dr. Griffiths said that he made very careful inquiry upon this head with negative result.—Mr. T. Smith suggested that the child might have taken steel wine when suffering from infantile paralysis.—Dr. Griffiths replied in the negative.—Mr. Parker referred to a case of a boy nine years of age which had been in the Hospital for Sick Children, under the care of Dr. Dickinson. In this case the boy had been in the habit of carrying his father's dinner to a cab-stand, and the father had constantly induced the boy to take spirits. There was marked ascites, with retraction of the liver.

Dr. Greenfield brought forward some fresh specimens of Visceral Syphilis, obtained from a female twenty-five years of age, who had suffered from syphilitic disease of the palate for four years. Death occurred somewhat suddenly after an attack of left hemiplegia with spasm of the affected muscles. Examination showed extensive syphilitic disease of the cerebral arteries, and the specimens brought forward included the spleen, kidney, and liver, which were the seat of numerous gummata. One of the kidneys was completely infiltrated. Dr. Greenfield proposed to bring forward the results of his microscopical examination of these organs, and of the arteries, on another occasion.

The Society then adjourned.

Reviews and Notices of Books.

On Addison's Disease. Being the Croonian Lectures for 1875. Revised and Illustrated. By Edward Headlam Greenhow, M.D., F.R.S., F.R.C.P., Lecturer on the Principles and Practice of Medicine at the Middlesex Hospital. London: Longmans and Co.

This work, as the title indicates, consists of the Croonian Lectures at the College of Physicians on the subject of Addison's Disease, delivered in the spring of the present year. The book contains, however, much more than the original lectures, which were published in full in our columns at the time of their delivery, and will therefore be fresh in the memory of many of our readers. To these, which constitute, in fact, only the first half of the work, we have two valuable appendices, the first containing the detached reports of thirty-seven selected cases given as evidence of the facts on which the conclusions are based, and the second a reference to the 333 cases of disease of the suprarenal capsules of which the author has been able to discover a record. The work is also enriched with excellent coloured plates representing the naked-eye appearances of the tongue and of the diseased capsules, and also of the microscopical appearances of the skin and mucous membrane and of the diseased capsules, the former chiefly by Mr. Henry Arnott, and the latter from the pencil of Dr. Sidney Coupland. The appendices and plates alone, therefore, give a great additional value to the book.

There is scarcely any disease in the whole range of medicine in which a greater variety of problems is involved, the elucidation of which requires wide study both of the special disease and of other morbid conditions; and, whilst the fascination of the subject has led many to frame hypotheses as to the connexion of the several parts of the disease with each other, many of these have been grounded only on individual cases. And there is scarcely any other disease the history of which shows so clearly the fallacies which may arise from imperfect observation and hasty generalisation from individual cases, and the necessity of a strictly logical inquiry. In the opinion of some, the evidence seemed to prove that Addison's disease had no essential connexion with disease of the suprarenal bodies, and still less with any specific affection of these organs. Dr. Greenhow has, therefore, done great service in collecting and comparing all the available evidence, and sifting it in such a way as to show how far our knowledge at present goes and on what points we are yet in default, and in thus clearing the ground for future investigation.

In his first lecture, after a slight outline of Addison's life and of the history of his discovery, Dr. Greenhow gives a description of the clinical features of the disease with the varieties in its symptoms and progress, and of the morbid anatomy in well-marked cases. These, especially the latter, are for the most part remarkably clear and good, but on the subject of temperature, with the exception of the statement that it sometimes falls considerably below normal in the last stage of the disease, we find no information, possibly from want of recorded observations. In the second lecture the question of the association of a special morbid condition of the capsules with the bronzing of the skin and the general symptoms is discussed; the several classes of cases which have led to erroneous views are also in turn considered, and the various fallacies involved exhibited, the conclusion being that there is an essential connexion of the special disease of the capsules with the general symptoms and the melasma, but that of the latter either may precede the other. It is this lecture which we would especially commend as of value, from the thoroughness of the investigation and the clear light in which the facts are placed, and we believe that Dr. Greenhow's conclusions may be accepted as correct. In the third lecture the author takes up the difficult problem of the intimate pathology of the disease, and of the relation of the capsular disease to the melasma and the general symptoms. After showing that they cannot be due solely to the destruction of the tissue of the capsules, as these may be destroyed by other morbid growths without symptoms, and in Addison's disease itself the symptoms bear no direct proportion to the extent of the morbid process, he accepts the view which is now usually adopted, that they are due to nervous lesions, either by the affection of nervous filaments in the capsules themselves, or more probably by the secondary implication of the nerve trunks and ganglia of the solar plexus and its neighbourhood, and particularly of peripheral branches of the pneumogastric nerve to the plexus and the capsules. The bronzing of the skin he also believes to be due to reflex irritation through the cerebrospinal nervous system, and not to a morbid condition of the blood. In coming to these conclusions, the facts deduced from the morbid anatomy, the clinical features, and physiological facts are all carefully considered. The difficult subject of etiology is next discussed, and Dr. Greenhow shows that in a certain number of cases the disease has apparently originated by extension of inflammation from disease of adjacent parts, especially psoas abscess and disease of the lumbar vertebræ; whilst in others it has been traced to a blow or strain. And he points out the important fact that it is of far more frequent occurrence in those classes whose occupations subject them to the risk of such injuries. These facts are suggestive, and may ultimately lead to a more definite knowledge of the causes of the disease. On the question of the nature of the morbid growth Dr. Greenhow is wisely reticent, and does not give his adhesion to the view that it is tubercle, whilst laying due stress on the large percentage of cases in which phthisis has coexisted with the disease. In the present state of knowledge this seems the wisest course, especially remembering the large percentage of phthisis in diabetes. Diagnosis, prognosis, and treatment are summarily dismissed in two pages, and we observe with regret the absence of an index; but these are only small and remediable defects in a work of great value, which will long be the standing work of reference on the subject, and will possess a permanent interest for all future workers.

Transactions of the Clinical Society of London. Vol. VIII. 1875.

THE present volume of Transactions of this young and flourishing Society is but little inferior in interest to any of its predecessors. It contains, in addition to the Address of the President, forty-six papers, for the most part consisting of brief records of cases, many of which possess a permanent value. It is true that the volume is of far more modest character than those of the Pathological and Medico-Chirurgical Societies; but it must be remembered that whilst the latter Societies exist rather for the permanent record of ascertained facts, the Clinical Society has from the first devoted itself more to the discussion and elucidation of clinical cases of interesting or doubtful nature. Thus it not infrequently happens that the case related forms only the text of a valuable discussion, in which other cases of even greater value are narrated, and the result of the debate is often to place the original case in a very different light from that in which it had been viewed by the author. Of all this there is no record in this volume of Transactions, which, therefore, does not really represent the great value of the Society.

It is unnecessary for us to enter into the merits of the various cases individually, all of which have been recorded, and many commented upon, in our columns. Some of them will be long remembered on account of their pre-eminent rarity, recording isolated cases which would seem to upset all our former clinical experience; such as the case of high temperature, related by Mr. J. W. Teale, which, although enshrined in this volume, will yet, we imagine, be the subject of rational scepticism until confirmed by further cases of a similar nature, carefully investigated. Of other cases of great interest from their novelty, we may note one of creeping eruption, shown by Dr. R. J. Lee, on which we have also a valuable report by Drs. Dickinson, Tilbury Fox, and Dyce Duckworth. Some of the cases are noteworthy rather from their inordinate length as contrasted with their value; indeed, some of the most valuable cases are those which are most briefly and concisely narrated. It would perhaps seem invidious to select examples of this kind. It should be remembered that, as the cases are usually read in full, the discussion is commonly of far more value when the cases have been clearly and briefly put, in such a manner that the main features are fully apprehended, and the attention is unwearied by needless detail. That "brevity is the soul of wit" might well be adopted as a motto by the Society.

With regard to the general arrangement of the volume, it would, we think, be an advantage if the papers were classified under their subjects instead of being placed in chronological order; this would increase their scientific value.

Finally, we have a word to say about the way in which the work has been edited, if, indeed, there has been any editing at all, of which we have no sufficient evidence, external or internal. But whoever may have been responsible has been guilty of serious negligence. First of all we have a list of contents, in which certain errors strike the eye at a glance, and make us afraid to examine more fully. Thus we have a heading of "Severe Epilepsy, *caused* by excision of Neuroma," which, as may be supposed, turns out to have been *cured* instead of caused. Then a case of poisoning by "Hydral Chlorate," a name with which we are not familar, but which turns out to be a synonym of chloral hydrate. And not only is this name repeated in the heading of the case, but we find the case carefully indexed under both titles, lest there should be any confusion from the use of the new term. The index itself is a curious compilation which will well repay a careful and critical study, having apparently been constructed by the "printer's devil" with the aid of a kaleidoscope, and a table of permutations and combinations. The system, if system it be, which has been followed, appears to have been to enter every case as a case of every separate symptom to be found in the title, as well as in full, and under the author's name—a system which of course increases the number of cases, and introduces some novelties. Then we have such errors as "larnyx," "pharnyx," &c., which greatly increases our suspicion as to the origin of the index. Unless an index is to be of some value, it would be better to omit it altogether in future volumes, at any rate until a responsible editor is found for the work.

A Manual of Physiology. Being a Course of Lectures delivered by Prof. Küss at the Medical School of Strasbourg. Edited by MATTHIAS DUVAL, and translated from the Second and Revised Edition by ROBERT AMORY, M.D., formerly Professor of Physiology at the Medical School of Maine. London: Baillière, Tindall, and Cox.

A SOMEWHAT hasty glance at the contents of this new Manual of Physiology has led us to form a favourable opinion of it. Less bulky than Kirkes and Paget's treatise, or than Dr. Carpenter's smaller work on Physiology, it represents the French rather than the German side of this subject. It is, at the same time, clearly written and fairly readable for a translation. Too much stress appears to be laid upon the importance of the epithelia. The corpuscles of the blood, of nervous-tissue epithelium, &c., are constantly and erroneously termed globules, and statements are sometimes made which, however probable they may be on *a priori* grounds, should not be dogmatically asserted in a work intended for students. As, for instance, when (p. 121) it is stated that "the principal object of the functions performed by the blood-globules is to excite or support the nervous system, as the nerves can exist only where the blood-globules are properly constituted, and contain the necessary quantity of oxygen gas." We imagine many facts in comparative anatomy militate against this much too positive statement. So, again, the curious views of Rouget on muscular fibre, to the effect that it is a true spiral spring which, actively distended during the repose of the muscle, returns upon itself at the moment of contraction, and hence that muscular contractility is a purely physical property of elasticity; and much more in the same strain is given as though it were proven, instead of being, as it really is, purely hypothetical. If some objectionable features of this kind, which might easily be expurgated by an able editor, were removed, Dr. Amory's translation of MM. Küss and Duval's work would prove very serviceable. It contains much that is not contained in any other treatise in the hands of the English reader. The theory and laws of the reflex actions are well given, and, on the whole, a due proportion is maintained between the several subjects. The numerous woodcuts, which are for the most part of a diagrammatic character, are exceedingly good, and materially elucidate the text. Though we do not believe the work, which we understand is having an unprecedented sale in America, will supersede our own text-books, we do think it may be advantageously read with them.

A System of Midwifery. By WILLIAM LEISHMAN, M.D. Second Edition. Glasgow: Maclehose. London: Macmillan.

IN about two years after the first issue of this excellent treatise a second edition has been called for. The work has undergone general revision and correction, but alterations have been chiefly made in the chapters on Physiology and Puerperal Fever. It will be remembered that in the first edition the view that puerperal fever was "a disease belonging to the so-called zymotic class, the proximate cause of which is some peculiar poison to which lying-in women are liable by contagion, or which is under certain circumstances developed in the puerperal state," was adopted. At a meeting of the Obstetrical Society, held last session, at which puerperal fever was the subject of debate, Dr. Leishman stated that he had found reason to renounce the above view. How complete this change of opinion has been will be seen from the following passage from the present edition:—"The first question to be determined then is, does such specific poison exist? or, in cognate terms, does any such disease occur as specific puerperal fever? To this question we do not hesitate to give a negative reply," &c. The view espoused now by Dr. Leishman is that the majority of cases of puerperal fever are of septic origin, and that the septic poison is communicated to the patient by attendants, or generated in the patient's own body by decomposition of the discharges occurring after labour; other cases are due to the poison of acute specific diseases, typhus, typhoid, &c. In the latter case the disease may run the course of that with the poison of which the patient has come in contact, but more frequently it runs the course of puerperal fever. To this view we subscribe our entire adherence. These chapters give a full and complete account of the symptoms and treatment of puerperal fever, but we cannot help remarking that they want more vividness of description.

We regard the treatise as thoroughly sound and practical, and one which may with confidence be consulted in any emergency.

Medicinal Plants. Parts I. and II. By ROBERT BENTLEY, F.L.S., and HENRY TRIMEN, M.B., F.L.S. London: J. and A. Churchill.

ALTHOUGH the day of the medical herbalist has passed away, and treatises upon so-called "medical botany" have been replaced by works on the general science itself, without respect to the materia medica, yet we gladly welcome this present publication as a valuable addition to medical literature. It has started upon the most catholic principles, it being the intention of the authors—than whom none are more fitted to undertake it—to make their work a kind of illustrated companion to the pharmacopœias of the world. It will, when completed, thus comprise a collection of drawings of medicinal plants unrivalled in extent and character. These first instalments promise well for the work, which of course will be better judged when it shall be published in full. They comprise no fewer than fifteen faithfully coloured plates of various plants, some of which have never been figured before, and the letterpress accompanying each plate is a concise and clear account of the botanical features of the plant, its medicinal properties and preparations. The English reader will be greatly enlightened by the appearance of this publication, in that he will hear for the first time probably of many plants whose virtues have found expression in the Pharmacopœias of India and the United States.

The plates strike us as being executed with a faithfulness and clearness of outline which leave nothing to be desired, and we trust the enterprise of the publishing firm in issuing them at so cheap a rate will be fully repaid.

Diaries.—At this season of the year we usually receive copies of diaries of various sorts for inspection. We give the first place among those we have already received to "The Physicians' and Surgeons' Visiting List," published by Messrs. John Smith and Co., of Long-acre, upon a plan furnished to them by Mr. Seymour Haden. In addition to being a diary, it contains a good deal of useful information, likely to be of service to the practitioner, concisely arranged. "The Chemist and Druggist's Diary" for 1876 fully maintains its reputation; it is published at the office of the *Chemist and Druggist Journal*. Messrs. Partridge and Cooper have sent "The Folio Scribbling Diary" for 1876, price 1*s.*; "The Diary and Call-book," price 2*s.*; and "The Octavo Scribbling Diary," price 2*s.*,—all interleaved with blotting-paper.

POST-MORTEM EXAMINATION OF THE REMAINS OF HARRIET LANE.

A Clinical Lecture, delivered at Westminster Hospital,

By THOMAS BOND, F.R.C.S., B.S. Lond.,
ASSISTANT-SURGEON TO THE HOSPITAL AND LECTURER ON FORENSIC MEDICINE.

Gentlemen,—As you probably are aware, I was employed by the Treasury to make the post-mortem examination upon the human remains found in the possession of Henry Wainwright. I was at once fully impressed with the grave nature of the task committed to me, and approached it with a mind absolutely free from any preconceived ideas as to the guilt or innocence of the prisoner. This condition of mind it was of course necessary to maintain during the whole of the inquiry, as it was my business to interpret facts only, quite regardless of the result to the prisoner.

On the 16th of September I met Mr. Larkin, who had already made a preliminary examination, and had given certain evidence before the magistrate. He had removed the abdominal and pelvic viscera, and very properly had placed them in jars which had previously been cleansed with distilled water. He had very carefully taken off the skull-cap without injuring the dura mater or brain; he also discovered a cut in the throat, to which he attributed death. But I proceeded to the investigation methodically and carefully, without troubling my mind with any theory or preconceived opinion.

There were, of course, two main questions to determine:—1st, the cause of death; 2nd, the identity of the remains.

I found the body in a sealed coffin, the lid of which was partially of glass. This was a very convenient method for exposing the body to the jury, and also to the relatives. I had the remains removed from the vault into the yard, and on opening the lid the horrible and peculiar smell at once indicated an advanced stage of decomposition. Availing myself of Mr. Larkin's valuable assistance, I proceeded to the examination. The remains were laid on a table in an open yard, with a good light, and carefully placed in position. They consisted of ten pieces. (1) The head and neck, which was separated from the trunk between the sixth and seventh cervical vertebræ; (2) the trunk, including thorax, abdomen, and pelvis; (3 and 4) the two thighs, divided from the pelvis through the neck of each femur; (5 and 6) the two legs with the feet attached, separated from the thighs at the knee-joints; (7 and 8) the two arms, which were cut off at the shoulder-joints; (9 and 10) the two hands, one being separated at the wrist and the other about two inches above. There was also found adhering to the body a quantity of white greasy material mixed with earth, which I subsequently found by chemical examination to be chloride of lime. This, I have no doubt, in a great degree contributed to the preservation of the superficial parts of the body, by the formation of a coating of adipocere, which is the result of a chemical combination of a fatty acid with a mineral base, generally supposed to be ammonia, when the tissues become changed into adipocere; but in this case the base was probably lime. Where this covering of adipocere was deficient the flesh had eroded in patches. At other parts it had dried, appearing white, silvery, and smooth, as if stretched over the subjacent tissue. It certainly gave me the idea at first of numerous scars, similar to those produced by slight scalds. This appearance played an important part at the trial, as Mr. Aubin, the surgeon for the defence, cut out one of the patches and called it a scar.

From the nature of the hair, the shape and contents of the pelvis, and the slender limbs, it was evident at once that I had before me the complete body of an adult female, and that it had been hacked apart by a rough and unskilled hand. The woman had evidently been dead many months, for the face, the front of the thorax, and part of the abdomen were quite decayed. No trace of features could be distinguished, although Mr. Larkin made the discovery that the ears were pierced for earrings. The limbs, however, and the lower part of the abdominal walls were covered with the dark-brown greasy substance which I have described as adipocere, and on scraping away which, the skin underneath was found well preserved, but in a dry and shrivelled condition. The thoracic, abdominal, and pelvic viscera, with the exception of the uterus, were so much decomposed that no examination was made of them, but the condition of the uterus was accurately noticed. It was very small, not above an inch long, and not a quarter of an inch in thickness. The colour was very dark brown, and to the touch it felt like soap. It was carefully put aside and soaked in water for subsequent examination. The division of the body was undoubtedly of recent date, as proved by the freshly cut bone and muscle, the former hanging about the cut parts in chips, and the latter flaccid and not retracted from the cuts. The cutting seemed to have been done by a blunt adze or chopper, and the appearances were consistent with its having been done with a hatchet shown me by the police. The scalp was partially separated from the skull, and more particularly so on the right side, and attached to it was a quantity of curly auburn hair, which was fixed at the back of the head to a pad by a number of hair-pins. On the left side of the head the hair was clotted with a dark substance resembling dried blood. The sutures of the skull were well marked and distinct, with the exception of the frontal, which was quite obliterated. On the right side of the skull, just above the articulation of the posterior inferior edge of the parietal bone with the squamous portion of the temporal, there was a depressed fracture, the size of a sixpence, and at the back part of the depressed bone there was complete penetration of the skull by a hole large enough to admit a small bean. The fracture must have been caused by a hard, blunt substance, striking in a direction obliquely backwards and inwards. The fracture was not of recent date, the broken surfaces being of dark colour, and similar in appearance to the exposed portion of the skull. The depression was not easily seen at first sight, as it was filled up with a dark substance similar to that found about the body—viz., chloride of lime and earth, which was probably here mixed with blood. The fracture was somewhat stellated, but it did not extend into the lateral sinus.

The scalp was detached over the fracture and around it for a distance approximately of two inches, exposing the bone. There was a penetrating wound of the scalp, and when drawn forward the hole corresponded to a point on a level with, but an inch posterior to, the fracture. The under surface of the scalp around the hole was dark-coloured, and its substance infiltrated with blood to a depth of one-sixteenth of an inch. The under surface of the uninjured portion of the scalp was of a pale-brown colour. The dura mater was detached from the skull-cap and entire, except opposite the fracture, where it was perforated. Its surface was of a light-grey colour, but exactly opposite the fracture it was very dark brown, and appeared thicker. On cutting through the membrane at the point of puncture, the dark colour was found to extend through to the under surface, and the brain in contact with it was dark-brown for a distance of half an inch around the hole. This was caused, I had no doubt, by infiltrated blood, and I therefore formed the opinion that the injury was inflicted during life. On passing my finger through the hole in the dura mater into the substance of the brain, I found two spiculæ of bone. I enlarged the opening in the dura mater, and carefully removed the decomposed brain, which was in a semifluid condition, and of a light-brown colour; then carrying the exploration on in the direction of the hole through the skull, I found a much flattened bullet lying in the left hemisphere of the cerebellum. It must have entered the skull obliquely, from before backward, and had struck the occipital bone just behind and on the left side of the foramen magnum, causing a slight stellate fracture of the inner table. This bullet undoubtedly caused the injuries I have described. On removing the dura mater and the soft pulpy brain I discovered a second bullet lying on the posterior clinoid processes of the sphenoid bone, which were both broken off. This bullet was slightly flattened on the top only, and appeared to have entered the skull by direct impact. On further examination, I found a hole in the skull exactly above the base of the zygomatic process of the right temporal bone, and, passing my finger directly inwards along the base of the skull, and in a line with the petrous portion of the temporal bone, I found a large spicula of bone half-way between the hole and the position of the bullet. I found no appearance of effused blood in the track of this bullet inside the skull, but found a quantity of dried blood around the external opening just in front of the ear. I formed the opinion that this wound was probably inflicted directly after death, as I should have expected to find evidences of blood in the track of the bullet had it been fired during life. The injury was of old date, and probably inflicted when life was ebbing, or directly after death.

A cut two inches long extended from the right side of the thyroid cartilage upwards to the left angle of the lower jaw, dividing all the tissues down to the vertebræ. The larynx was partly divided, and the cut, shallow and superficial at first, enlarged towards the left, and went deeply upwards under the angle of the jaw. It nearly divided the body of the third cervical vertebra, and extended through the transverse process on the left side. The surface of the wound was retracted and dried, quite the reverse of the flaccid and soft appearance of the cuts separating the limbs and trunk. It appeared to have been inflicted from the front, upwards and backwards; it was a clean cut, and must have been done with a sharp instrument. The incision in the vertebra was dark and dry at the edge, but the deeper portion was clean and very fresh-looking. I saw no appearance of blood in the wound, but there was a quantity of clotted blood around the left ear, and the hair on that side was matted together with blood. I could form no opinion as to whether the cut was inflicted during life or after death, but it certainly did not appear a recent cut. About the cut in the vertebra I was much puzzled. The fresh-looking and moist surface of the deeper part of the cut seemed to indicate recent infliction. I decided to give no positive opinion with regard to the wound in the throat. I believed it to be of old date, but I could not swear that it was not done in cutting up the body, especially as the tissue of the face and neck was much drier than the other portions of the body, and the parts had necessarily been somewhat more exposed during the careful examination of Mr. Larkin in the preliminary examination.

There were four teeth absent from the mouth—one upper incisor, one canine, and two lower incisors. They had evidently fallen out during decomposition. The canine and one of the lower incisors were afterwards found and replaced. The first bicuspid of the upper jaw was decayed to the root; all the other teeth were sound. The wisdom-tooth of the left upper jaw was still uncut, and the mucous membrane had to be removed to expose it. The upper incisor was slightly prominent. The cartilages of the ribs were not at all ossified. The bones of the skeleton were light and small, the cancellous tissue abundant, and the articular surfaces were cartilaginous and soft. The epiphyses had united at the parts I examined—viz., the neck of the femur, the head of the humerus, and the articular surfaces of the tibia. From the above appearances I inferred that the age of the deceased was from twenty to twenty-five years.

The above is the substance of my report to the Treasury after my first examination. The subsequent examinations were made in the interest of the prisoner and in the presence of Mr. Aubin, a surgeon appointed to watch the case for the defence. My acknowledgments are due to Mr. Aubin for the courteous behaviour and proper spirit with which he approached the investigation. During the course of it three more important observations were made. First, the discovery of the scar, which I was induced to look for through having heard Mr. Lane say before the magistrate that his daughter had a scar on one of her legs, but he did not know which. I first scraped the adipocere from the left leg, and failed to find one, but on carrying out the same process on the right leg, found most unmistakably a raised fibrous scar situated exactly over the fibula, about two inches below the head. It was about the size of a shilling, rather elongated from above downwards and backwards. The skin in front was healthy, but much puckered and drawn, and at the back there was the usual white discolouration found after a burn or scald. The fibrous portion was brown and raised, almost keloid in its character, being at least an eighth of an inch thick.

We next turned our attention to the hands and feet, which were exceedingly slender and much dried; the nails were long, and there was no mark of a furrow on the ring finger. The feet measured eight and a half inches, and on comparing them with a boot of Harriet Lane's it was evident it would fit. Finally, we adjusted the parts as accurately as possible, which was not easy, owing to one or two vertebræ in the neck having got loose, and from the chopping up of the neck of the femur, which rendered it very difficult to fix the thighs in the exact anatomical position; however, we did our best, and after several trials found the exact measurement of the height was 4 ft. 11½ in.

I took possession of the third cervical vertebra and of the scar. I also cut off some of the hair, which I afterwards compared microscopically with some hair taken out of the grave at Whitechapel by Inspector Fox, and likewise with some hairs found on a hatchet and spade. Mr. Larkin took charge of the uterus, and of the pad and hair-pins found at the back of the head, in which he found subsequently a bullet flattened against the hair-pins.

(To be concluded.)

THE WATER-SUPPLY OF THE METROPOLIS.

NEARLY a hundred pages of the last Report of the Rivers' Pollution Commission are devoted exclusively to the past and present history of the water-supply of the metropolis. The quality of the London water has been the subject of many investigations, and as long ago as 1828 a Royal Commission was appointed to inquire and report upon the subject, and a more complete system of filtration was recommended. It was found, however, as had been predicted, that mere filtering could not, and does not, remove organic matters in solution, and that when the Thames, during heavy rains, received the flushings of the sewers, streets, and cesspools, the drinking-water supplied was often execrably bad in quality. No changes as to the intake were, however, made until 1848, when the Lambeth Company obtained an Act authorising them to remove their intake from Lambeth to Thames Ditton, above Teddington-lock, and consequently beyond the reach of the London sewage. In that and the following year the metropolis was severely visited by epidemic cholera, and in 1850 the General Board of Health (consisting of Lords Carlisle and Ashley, Mr. Chadwick, and Dr. Southwood Smith) reported decisively that in consequence of its hardness and its various modes of pollution, the Thames water ought to be abandoned for domestic purposes. In the following year another Commission was appointed to examine into the proposed new sources of supply, and the unfitness of the water procured both from the Thames and the Lea having been further demonstrated, an Act was passed in 1852, providing, among other things, that no water shall be taken by any company supplying the metropolis below Teddington, or from any tributary of the river within the range of the tide; that all storage reservoirs within five miles from St. Paul's shall be covered, and all water supplied for domestic purposes filtered. The immediate results of this Act were to remove the intakes of all the companies above Teddington-lock. The East London Company also moved its intake beyond the reach of the tide in the Lea, and the Kent Company, having abandoned the polluted Ravensbourne, obtained its supply henceforth from deep wells sunk into the chalk. These alterations effected a very material improvement in the quality of the water supplied to London, and the result was a great saving in human life during the subsequent cholera epidemics of 1854, and especially of 1866. Official inquiries were again made in 1856 and 1857, with no very special results, and in 1865 the first Rivers' Pollution Commission was appointed. The report appeared in the following year, and the evidence shows most indubitably that, as regards both the Thames and the Lea, the water is polluted above the intakes of the various Companies by the sewage of the towns through which the streams flow, as well as from drainage of the land and other sources. Some very unsavoury details are given in the report before us relative to the Lea, from which the East London Company still take their water, and since 1866 no amelioration has taken place in the condition of the river. The next Commission, which was presided over by the Duke of Richmond and consisting of Sir John Thwaites, Colonel Harness, Sir Benjamin Phillips, Mr. T. E. Harrison, and Mr. Prestwich, reported in effect "that there is no evidence to lead us to believe that the water now supplied by the Companies is not generally good and wholesome," and that "when efficient measures are adopted for excluding the sewage and other pollutions from the Thames and the Lea and their tributaries, and for ensuring perfect filtration, water taken from the present sources will be perfectly wholesome." Experience, however, teaches that these last conditions are wholly impracticable. A large amount of evidence as to the transmissibility of certain diseases by the agency of water and other kindred subjects is quoted by Mr. Simon, Drs. W. Farr, Parkes, Odling, Playfair, and Angus Smith, and elaborate analytical tables are appended, showing the comparative quality of the various waters supplied. London is at the present time supplied by eight private companies, six of which take their water exclusively from the Thames and Lea. The New River Company takes the water it distributes chiefly from the Lea, but partly from springs and deep wells, and the Kent Company supplies deep-well water only. This last, the only really good supply (and the only one which the Commissioners recommend should be retained) is obtained from wells situated at Deptford, Charlton, Plumstead, Crayford, Shortlands, and Belvedere. Upwards of 42,000 houses are thus supplied with about 9,000,000 gallons of water daily. The shafts of these wells are lined with cast-iron cylinders from 70 to 100 ft. in depth, and are thus properly protected against surface infiltration, and from the bottom of the shafts bores are taken to the full depth of the wells. The Commissioners remark that the sole defect of this water is its hardness, and record an opinion that "the supply of such water, either softened or unsoftened, to the metropolis generally, would be a priceless boon, and would at once confer upon it absolute immunity from epidemics of cholera." There are, however, besides the sources of supply abovementioned, a large number of public pumps drawing their supplies from shallow wells. In 1872 a return of these wells was moved for by Mr. Kay Shuttleworth, and analyses of waters taken from them proved them to be, with few exceptions, highly infected with all kinds of contamination. The water of only three of these wells is, as we recorded last week, fit for drinking purposes. The chapter closes with a detailed description of a scheme, by Mr. J. F. Bateman, for bringing to London some of the hard waters of the Severn, and one by Mr. G. W. Hemans and Mr. Hassard for a supply from certain lakes in Cumberland. The estimated cost of the former would be about eleven and of the latter more than twelve millions. But the Commissioners give strong reasons for their opinion, "that the whole of the metropolis and its suburbs should be supplied exclusively with the spring and deep-well water of the Thames basin," because it is excellent in quality, abundant, and within a moderate distance of the metropolis.

TRICHINOSIS.

EPIDEMICS of trichinosis are not frequent, but those which occur and are recognised are so wide spread as to render it increasingly evident that the disease has obtained and maintains no limited foothold. From the east and the west news of its occurrence reaches us. In Germany, indeed, its existence seems to be well looked for, and a corresponding decrease in the disease may be expected. It is evident that its ravages have been already checked by careful scrutiny of pork. In the district of Brunswick, according to the report of Dr. Uhde, only twenty affected pigs were found out of a total examined of more than 100,000. Eighteen of these were, however, found in the city of Brunswick. But from America the account is less reassuring. We have received from Dr. Sutton, of Aurora, Indiana, an instructive account of a carefully investigated outbreak of the disease which occurred in that town in 1874, in which nine persons were attacked, three of whom died. The disease in each could be traced to the same cause; all had eaten of some uncooked smoked sausages made from the meat of a pig which was subsequently shown to be full of trichinæ. The symptoms were mainly those of gastro-enteritis; muscular pains were conspicuous in only a few instances. In one of the fatal cases, however, the muscular tenderness was so great that the patient could scarcely be moved, and persistent general œdema was very marked. In this case examination of the patient's muscle after death showed it to be so crammed with trichinæ that their numbers were estimated at 100,000 in every cubic inch. In the other two fatal cases, although the circumstances of outbreak and symptoms were the same, scarcely any trichinæ were found in the muscles, the post-mortem appearances being those of gastro-enteritis. One or two trichinæ were found in the intestinal wall. In the first case the general œdema and muscular tenderness occurred in ten days from the onset of the gastric symptoms, and as a week is considered necessary for the development of the young trichinæ in the alimentary canal, their diffusion into the system must have been effected with great rapidity.

The resemblance of the symptoms in two of the fatal cases, and in those which were not fatal, to a simple inflammation of the alimentary tract, is a fact of much importance, which was further confirmed by experiments on dogs. Its importance lies in the fact that while trichinosis had no place in the Registrar-General's returns in America a few years ago, dysenteric and enteritic affections produce a great number of deaths, and Dr. Sutton brings forward facts to show that a considerable proportion of the pigs killed in the Western States are affected with the disease. Microscopic examination of the flesh of several thousand pigs killed in South-eastern Indiana showed that from 3 to 16 per cent. were affected with the disease. The Western States are the chief pork-producing districts. It is estimated that in them five million pigs are killed and sent away each winter, their flesh being the chief animal food of a large portion of the population of the United States. If only 4 per cent. of these pigs are diseased the number of affected animals annually sent to the American market is upwards of two hundred thousand! If it be true that in 90 per cent. of the cases of trichinosis the chief symptoms are intestinal, trichinosis may have been effecting serious unsuspected ravages for many years.

With reference to the alleged identity of "hog cholera" and trichinosis, careful examination of the flesh of six animals dead of the former disease failed to show the slightest evidence of trichinæ, and the two diseases are therefore regarded by Dr. Sutton as distinct. Three out of four cats fed on diseased meat were found to be swarming with trichinæ; in none of forty-two rats and of eight moles examined could any trichinæ be found.

THE LANCET.

LONDON: SATURDAY, DECEMBER 11, 1875.

The representatives of the English Examining Bodies interested in the formation of a Conjoint Board held a meeting on Friday, the 3rd instant. The meeting was private and deliberative. Nevertheless, we presume that we shall not do any harm by announcing that the general feeling of the representatives was decidedly favourable to the scheme. It was resolved to invite the Society of Apothecaries to send two representatives to the conference. Hitherto this Society has been incapable of joining in the negotiations. It has lately been empowered to do so, as our readers know, by a special Act of Parliament; and, as the will is not wanting, we may expect its representatives to be present at the next meeting of the Conference, to be held on Thursday, the 23rd inst. It was further resolved, at the late meeting, to request the College of Surgeons to state what changes it desires in the scheme agreed to by the Committee of Reference. The College will probably make a statement of such changes, which will be considered at the meeting on the 23rd.

It seems to be felt on all hands that the present opportunity of effecting a practicable Conjoint Scheme may be a final one, and ought therefore to be seriously used. There is an impression abroad that any difficulty which now remains rests with the Royal College of Surgeons, who are supposed to be tenacious of their influence in the nomination of Examiners in Surgery. The Conference has taken a respectful course in asking for a formal statement of the views of the College. We must remember, too, that the present Conference takes place on the invitation of the President of the College of Surgeons. Taking all these things into consideration, we are hopeful that we may soon have to announce that differences have been removed and rival feelings and claims adjusted. Whatever may be thought of the probable working of a Conjoint Scheme in England, there can be no doubt that the English bodies will gain much credit by agreeing to such a scheme. They will set an example which Ireland and Scotland will not find it easy to ignore. The College of Surgeons has most to lose by a Conjoint Scheme; but it has also much to gain. If it shows an obstinate resistance, it may retain its great privileges a little longer; but it will fare worse when inevitable changes do come. We hope it will show, at this supreme crisis, that it knows when to yield.

◆

The employment of the cold bath as a routine treatment in cases of fever has only of late years come into vogue in this country; and even yet it has been carried out but indifferently, and has not received the full amount of attention that it deserves. It is too often restricted solely to cases of hyperpyrexia, and its full value as a great and powerful antipyretic agent has yet to be appreciated. One of the greatest obstacles in the way of its employment lies in the trouble and disturbance involved in the procedure; but even these are but minor difficulties in the path which cannot prevent its general adoption if it be really of such value as its supporters make out. Professor Liebermeister has long been known as one of the highest authorities upon febrile diseases; and his article on Typhoid Fever in the new "Cyclopædia of Medicine" is one of the most valuable contributions to medical literature that have appeared in our day. We propose to review here the arguments which he adduces in this article in favour of the employment of the cold bath, taking occasion to point out in what direction his method departs from that usually followed in this country. The material he has had to work upon has, indeed, been vast; for, as he tells us, in six years—viz., from 1865 to 1871—no fewer than 1900 cases of typhoid fever passed under his care at the hospital of Basle! For the purposes of comparison, however, between the cases treated prior to the general adoption of the cold-water plan and those subsequently so treated, Liebermeister takes but 1743 of those cases; of which, 861 were treated under the old *régime*, and 882—the total of the last three years—upon the new system.

Starting with the axiom that by "far the greater number of those who succumb to typhoid fever die from the effect, directly or indirectly, of the fever heat," Liebermeister points out that antipyretic therapeutics must form the basis of the rational treatment of this (as of any other) fever. And chief among all antipyretics is to be ranked cold water, of which the history of its introduction as a therapeutic agent by Currie in the eighteenth century, its subsequent neglect, and its revival on the Continent in comparatively recent times, is now too well known to bear repetition. Brand and Jürgensen, however, deserve to be remembered for the active part they took in the advocacy of this method, and to them Liebermeister accords all due honour. He then proceeds to give brief but clear directions as to the best means by which such treatment can be carried out, premising that, although the main object is the abstraction of heat from the body, the manner of performance should be such as produces the desired result with the least inconvenience to the patient. We know no work, except that of Brand, wherein such rules are so precisely laid down as they are here. Authorities—in this country at least—differ as to the degree to which the water in the bath should be heated when the patient is first put in it—whether it should be, say, 90°, and then gradually cooled to 70° or lower; they also differ as to the duration of the bath—whether this should be prolonged until the temperature of the body falls to normal, or whether it should be comparatively short and reliance be placed on the subsequent fall (which invariably occurs) in the temperature of the body. We have known cases where, in spite of the cooling of the water, the time taken in the fall of the body temperature has been so slow that the patient has been kept in the water for an hour and a half, supported by stimulants, taken out almost in a condition of collapse, and requiring the application of external warmth to neutralise the depressing effects of the long immersion! Such treatment Liebermeister sternly discountenances, and, however much it may have produced the desired effect of reducing the temperature, it is surely at the expense of the patient. Moreover, in such cases, the reaction is often disagreeably sudden and severe, so that within an hour or two the whole process has to be repeated. The plan followed by LIEBERMEISTER is, in brief, this: The patient is wholly immersed in water at a temperature of 68° F. The duration of the bath does not exceed ten minutes, and in the cases of feeble persons the duration should even be reduced to seven or five minutes. A short cold bath, he avers, has much better effect than a prolonged tepid one; except, again, in the case of very prostrate patients, for whom a bath of 95° gradually cooled to 72°, as recommended by ZIEMSSEN, is to be preferred. The indication for the bath is the safe and sure one obtained by the thermometer, a temperature of 103° in the rectum or 102·2° in the axilla being the usual limit to be allowed before having recourse to the bath. The frequency with which the bath should be repeated is entirely governed by the same standard; and, other things being equal, the number of baths required will be in exact proportion to the severity of the fever, the severest cases requiring a repetition of the treatment every two hours; while in some instances, Prof. LIEBERMEISTER tells us, the total number of baths required by one patient during his stay in hospital exceeded two hundred. As a rule, however, four or eight baths per diem suffice.

We have dwelt thus fully on the directions of Professor LIEBERMEISTER because it seems to us of the highest importance that, if this treatment is to be introduced into this country with any measure of success, it can only be by the adoption of a uniform scientific method, and not by the restriction of the treatment to cases on the verge of death from hyperpyrexia, nor by a too blind adhesion to the belief that a mere reduction of the temperature of the body to the normal is all that is requisite. Before, however, urging the general adoption of these measures, which would have to be applied in almost every case of fever, it is but right that the evidence adduced in its favour by LIEBERMEISTER be considered. This we may now proceed to do.

First of all comes the question of the effect of the bath on the course of typhoid fever itself. Does it in any way hasten the process of recovery, and help in the elimination of the poison? To this question a negative answer must, we think, be given. And at first sight even facts seem to point the other way; not that the duration of a first attack is retarded, but that it renders the patient more liable to relapse. Thus LIEBERMEISTER gives a percentage of relapses of 7·4 before the introduction of this treatment at Basle, as against 9·4 after the innovation; while the mortality in the relapse was five times as great. But he at the same time points out a fallacy in taking these statistics, which are based on the whole number of cases under treatment; for he says that formerly the mortality in the first attack was higher than now. Taking, then, only those cases in which a first attack has been passed through, the relative proportions of the two percentages are diminished, being on this basis as 9 : 10·3, instead of as 7·4 : 9·4. It must be borne in mind that relapses may occur more frequently now simply because those patients would have died earlier had not the cold bath been employed. However, he believes the question to be an open one, the evidence being in favour of a progressive increase in the frequency of relapses *pari passu* with the more extended application of this method. The same fact has been noticed by BIERMER.

One other question of great practical import in the use of cold water in typhoid is that which relates to pulmonary complications, so frequent and so baneful in their effects. Here the balance of statistical evidence adduced by LIEBERMEISTER is strongly in favour of the treatment. Thus, using the same number of cases already mentioned, he has noticed that, whereas before the treatment the frequency of pneumonia was 7 per cent., with a mortality among those so attacked of 50 per cent., since the cold-water treatment the average frequency of this complication has fallen to 6·4 per cent., and its mortality to 30 per cent. This diminution in the fatal cases of pneumonia is one of the strongest arguments in favour of the general adoption of this method. A like satisfactory and well-marked diminution in the frequency and mortality of hypostatic congestion and other pulmonary complications has also been noted, so that he says with truth that "affections of the respiratory apparatus occur rather more rarely and run their course with less severity under the cold-water treatment than under any treatment which is not antipyretic."

There is no need to point out further the value of the bath as a sedative—its marvellous effects in calming delirium and all the series of nervous symptoms attributable to high temperature,—for these are well known and have been fully insisted on by all those who have recorded cases of hyperpyrexia so treated. Nor is there any need to point out how it acts in steadying and controlling the action of the heart, changing in a brief space a feeble thready pulse into a moderately full, regular, and soft one. The simple fact that remains from the study of such advocacy as is here presented to us by LIEBERMEISTER is: that, of all antipyretic agents, the cold bath stands pre-eminent (over even other modes of cooling—as by affusion, the wet pack, &c.) both as to its certain action and as to its ready application. We can do no more than urge our readers to the perusal of this valuable and suggestive monograph, which will do much to establish the "Cyclopædia of Medicine" in the high rank it promises to take. If every article in the fifteen (or more?) volumes contain as much original thought and clear statement as this one, the work will indeed be of enduring value.

THE publication of the Report on Sanitary Measures in India, 1873–74, enables us to illustrate from another point of view the observations we made three weeks ago suggested by the serious interruption of the Prince of WALES's tour in India on account of prevalence of cholera. Dr. JOHN SUTHERLAND, in the letters with which he has favoured us, taking exception to our observations so far as they related to the Army Sanitary Commission, has failed to note their precise significance. Dr. SUTHERLAND writes under the impression that our observations were prompted by a desire to support a particular theory of cholera diffusion. They had a much wider scope, and referred to the discussion by the Army Sanitary Commission of complicated questions of etiology, and the expression of opinions thereupon, from data which the Commission itself had shown to be, or which it should have been obvious were, worthless. This is no question of water theory or any other theory, of one disease or of another, but a question which lies at the root of sound investigation of every disease and condition of disease whatever. To take, however, Dr. SUTHERLAND's suggestion, the "water theory" in relation to cholera is readiest to hand to illustrate our meaning beyond the possibility of mistake. In the India Office Report referred to, the Army Sanitary Commission undertake to answer, among other questions put to it by Dr. CUNINGHAM, the Sanitary Commissioner with the Government of India, the following:—"Is there anything in the evidence given in my Report [referring to his Report of the Cholera Epidemic of 1872 in Northern India] to support the idea that cholera was spread by specific poison drunk in water?" To this the Commission replies: "Without prejudging the results of more extended inquiry, and supposing that every obtainable information on the subject during the epidemic of 1872 has been recorded, the Committee has been unable to discover any evidence in support of the conveyance of cholera infection in drinking-water." Now, the kind of information upon which this conclusion is founded is thus described by the Commission in its special memorandum on that Report (the italics are our own): "One section of the notes [of local inquiries attached to Dr. CUNINGHAM's Report] refers to local sanitary conditions accompanying the great mortality among British troops in 1872. These notes *purport* to have been drawn up at affected stations by local sanitary advisers, and yet we can find little to help us to reply to the main practical question raised by this Report—namely, what removable local conditions can be grappled with so as to diminish the susceptibility to cholera among troops in future. *In regard to some outbreaks no allusion is made to the subject. In most cases the information is limited to casual remarks about the drainage or about the wells.* As no reference is made to the condition of the water-supply, as shown in the reports on water analyses at the stations, there are no means of estimating the relations between the quality of water and the amount of cholera. *There is no evidence to sustain a current theory that cholera poison conveyed in water is the cause* [!] *of cholera.* So far as any real sanitary information is concerned, *these local reports contain little of any value.*" In other words, information of a nature which would have discredited an ordinary inspector of nuisances in this country, and which would be insufficient to meet the simple practical sanitary requirements that should result from the performance of his functions, is held by the Commission sufficient to enable it to pronounce an adverse opinion regarding a mode of diffusion of cholera which has the assent of the men most competent to judge in this country. The information, it should have been obvious, was worthless for any purpose whatever; how unutterably worthless is especially shown by Dr. H. BLANC in his account of cholera in Yerrowda Central Gaol this year, published in THE LANCET of the 21st August. Here, as in every other instance that we have yet seen where exhaustive inquiry has been made in India, the results have been the same as obtained in this country.

On evidence similar in character to that referred to above, the Commission has not hesitated to express the opinion that Dr. CUNINGHAM's Report "has brought certain important questions regarding cholera to an issue"; adding, that "the appeal now made sets aside all opinions and theories, and requires to be answered solely on facts." On like evidence the Commission itself discusses questions of immunity of districts from cholera, of the dormancy of the disease, of the significance of solitary cases, &c., and in each instance to set aside as doubtful or worthless European experience. So also it deals with questions of the distribution of small-pox &c., amusingly unconscious that opinions commonly taught in European medical schools, respecting which it affects to see doubts, have been formed with full regard to all the supposed difficulties which puzzle it. But in the recent India Office Report chief interest attaches to a memorandum of the Commission on enteric fever. Here, as in the case of cholera, the Commission proceeds to discuss the etiology of the disease, and to raise doubts as to the soundness of European teaching, upon information just as worthless as that which it used regarding cholera. For anything that appears to the contrary in the memorandum, MURCHISON might never have written. It first describes generally, and inaccurately, the common conditions of filth under which enteric fever is usually observed to prevail in England. Then it proceeds to inquire to what extent these conditions are observed at military stations in India, and, finding that they are not present in any gross amount, it infers that English opinion on the subject will not apply to Indian experience. The fallaciousness of this argument is apparent. It ignores wholly the experience of palaces, of barracks, of schools and other public buildings, and of fairly ordered English towns, such as Croydon and Eastbourne, which might have most fittingly been compared with presumably controllable and controlled military stations. The Commission quotes the Surgeon-General's opinion, that the evidence collected from medical officers' reports leads to the conclusion that the disease "could not be satisfactorily traced to any special local insanitary condition, beyond perhaps some defects of surface drainage." In illustration of this the Commission gives a summary of the reports on the sanitary state of stations in which enteric fever had prevailed, and this is the staple matter: Water—"quality *generally* good." "Drainage imperfect; present drains choked with grass." "Water ought to be filtered." Tank water—"several grave sources of defilement running into the tanks." "No *observed* sanitary defects." "Sanitary arrangements *generally* good." "Soakage into floors and defective drainage; *no special causes of enteric fever dwelt on*"—and so forth, in every instance. Upon these notes the Commission observes that they "*contain all that is at present known* as to the local causes of enteric fever"; but yet it considers itself justified in expressing doubts as to the well-ascertained results of European knowledge on the subject! Nay, more. Although the existence of enteric fever among the native population became first known only in 1873, the Commission writes as if this important fact had no bearing upon the question of the causation of the disease among the troops! Equally astonishing is the fact that it does not appear to have observed that the figures of the mortality from enteric fever among the troops quoted by the Surgeon-General is very high as compared with that of the male population at the same ages in agricultural districts of England.

The Army Sanitary Commission appointed to deal with sanitary works has done excellent service in this direction at home, in the colonies, and in India; but in undertaking to deal with questions of etiology it has taken upon itself a task for which, by its constitution, it is eminently unfitted. Nothing but mischief can arise from the factitious importance which it has given to certain opinions which have been recently broached in India on the etiology of cholera and enteric fever—not on account of the opinions, but on account of the encouragement thus offered to perfunctory inquiry and perfunctory sanitary supervision. The crude comments of the Commission act, as we have good reason to know, like a dead-weight upon Indian sanitary inquiry and work, discouraging the efforts of capable men; they, in fact and of necessity, from the important relations of the Commission to the India Office, largely neutralise the teaching of Netley. The gravity of sanitary questions in our great dependency requires very different treatment at the India Office. Under present arrangements sanitary questions and work in India are drifting towards hopeless confusion. To meet the exigency of the occasion, the India Office would do well to call Professor Parkes to its aid. His transference to the India Office as the head of a medical sanitary department, would best meet the present requirements of the India Office in medico-sanitary matters, and would best satisfy the profession and the public that due justice was being done to them. Professor Parkes might well be spared now from Nétley for this great work, and his presence in the India Office would infuse at once a healthier life into Indian sanitary administration.

◆

Mr. Secretary Cross has expressed an opinion that nearly all which can be done in the way of Sanitary Reform is to remove legal obstacles and help the masses to help themselves. Nevertheless, the passing of Acts of Parliament to facilitate the wise ordering of public or social affairs is not *legislation*. This should be borne in mind, because, while it is quite true that the best way to get a reform thoroughly carried out is to induce those who are responsible for the *status quo* to undertake its accomplishment, if the change needed is not entirely local and capable of being achieved by local action, trusting to local effort is sure to result in a want of harmony when the general effect comes to be realised. This is precisely the evil which is likely to ensue from permissive-law making in relation to matters medical. The concerns of public health are not of a class to be left to spasmodic local enthusiasm. The population is—like the old Hebrew symbol for people, water—subject to all the laws of transfusion and intermingling. Diseases spread; conditions of health or unhealthiness insensibly extend and become common to the whole community. The attempt to stamp out a malady in one locality, without applying the same or equally effectual measures for its extinction in other localities, is like the super-sagacious policy of Bumbledom, which, by the adoption of particularly severe labour-tests or imprisoning all the tramps and vagrants, in a single parish, drives the troublesome forms of pauperism into the next parish, and then claims credit for having performed a national service. No real good can be done, or a single satisfactory step taken in the interest of general public health, unless such measures are adopted as will reduce the sum of disease in the country at large, and this is not to be achieved by simply stimulating local zeal and enterprise. We do not mean to imply that local reforms are not useful in themselves, and in a very distinct degree tributary to the general advantage. No doubt, if every department did its duty, the national organisation, as a whole, would be largely benefited. But this is not the light in which State responsibility justifies a Government in treating the obligation to rule for the national good. Looking at the matter from the local standpoint, it is clear that every locality is bound by the code of honour, no less than by self-interest, to do the utmost within its means to advance the general welfare and prosperity. But looking at the matter from the central government point of view, it is necessary to treat the general need as calling for general measures to satisfy its requirements. An appeal to the males of the population to arm themselves, coupled with the grant of a small sum of money, by way of loan, to purchase arms, would not obviate the necessity of organising and maintaining a national army, even though it were required that a drawing of every firearm should be sent up to London to somebody to be inspected, confirmed, and signed. It may be desirable to encourage the formation of local corps of yeomanry and volunteer battalions, but nothing short of an imperial measure of defence would suffice to protect the empire against a formidable enemy. Precisely the same principle applies to the protection of the community against disease and the host of morbid influences which are rapidly tending to a deterioration of the stock and lowering the vitality of the nation.

We think it desirable to call attention to these very obvious considerations at this crisis, because there is already grave reason to fear that much of the local enthusiasm which fired up so rapidly under the first influences of the Artisans' Dwellings Act and the newly codified Public Health Acts will end with a mere flash in the pan. There are signs of exhaustion, which may issue in collapse. It seems as if the unaccustomed outburst of energy had used up all the strength. We hear of grand schemes of improvements being frittered away, of zealous officialism growing faint-hearted, of second thoughts being preferred to the good resolutions born of sudden convictions. It would be a great pity, and altogether a most deplorable and humiliating eventuality, if, after the generous warmth stirred by recent measures, there came a period of cold and selfish parsimony. There would not be so much danger of such a calamity if the Government of the day had not trusted wholly to the *vis a fronte*. As the case now stands, there is really nothing in the shape of *vis a tergo* except the medical officers' "representations"; and while we have great confidence in the wisdom and independence of medical officers of health, it is impossible not to recognise the extreme difficulty of their position, and the multitude of formidable obstacles which beset and embarrass a resolute and adequate discharge of their duties. It is not necessary to urge, more earnestly than we have already pleaded, the needs of the situation, or to incite these gentlemen to remember and perform the full extent of their task. That high sense of rectitude and fearless self-respect which have happily animated and inspired our profession in all public emergencies may be safely trusted to produce their proper fruit at this season. It is, nevertheless, impossible not to feel that too much has been devolved on men who, however self-sacrificing and energetic, are after all only human, and for the most part more dependent in fact than they may seem in theory. How very different would be the position of affairs at this moment if, instead of being wholly permissive, the Acts recently put in force had been compulsory. Besides the improved security for action to which we have already alluded, there would have been uniformity in the measures adopted. Something, possibly, may be gained by emulation; but this is a broken reed to lean upon. It would have been incomparably better if a visitation of localities, under central authority, had been made the basis of local action; thus relieving the local medical officer from the onus of initiating a costly scheme, which must often entail a loss of personal popularity, and supplying him with an incentive to exertion. As it is, everything in the shape of responsibility devolves upon the medical officer of the district, and with it goes the penalty of striving to reform where a tacit countenance of evil would, in nineteen cases out of twenty, be infinitely more agreeable to local authorities and district ratepayers. Then, again, why has the important question of payments to medical officers been left to those against whose financial interests these gentlemen may be required to act? Not only is there a conspicuous want of uniformity in the pecuniary value attached to the services of a medical officer of health in different districts, but the want of any guiding principle leaves each local authority to suit its own convenience, both as to the class of officer it selects and the manner in which his services are remunerated. It is important that these anomalies in the working of the Acts, bearing as they do upon the general result should be brought under the notice of the public, the profession, and the Legislature. We cannot but feel that the aspect of affairs is less encouraging than it was only a few weeks ago. Something very like a dead-lock has occurred in some localities, and in others there are tokens of wavering purpose and flagging zeal. It would be well if medical officers of health generally could be induced to speak out promptly and candidly in the professional press as to their difficulties. We shall be glad to hear their complaints, and strive to help forward the redress of their grievances.

◆

THROUGH the indiscretion of a contemporary the private, but imperfect, official list of the names of some of the gentlemen who are candidates for the new Board of Examiners in Anatomy and Physiology at the Royal College of Surgeons of England, was made public last week. It is scarcely necessary to say that, although that list was well known to us, we did not, for one moment, think of publishing it, partly in consideration of the feelings of those gentlemen who had applied for the office of Examiner, and partly because the document itself was of a confidential nature. We, nevertheless, feel at liberty to make some general comments on the nature and character of the applications, and to discuss the general merits of the applicants. It must, however, be premised that some important names have now to be added to the first list which may very materially affect the ultimate issues of the election. On looking over the names we are forcibly reminded of the difficulty that we foresaw and pointed out in a recent number. The list contains a large number of anatomists, some of whom have obtained a high reputation, and the selection must necessarily be difficult where the claims of many are so nearly equal. A due but not exclusive regard to the principle of seniority, and to the necessity of choosing the examiners from different schools, so that the two larger ones shall not be over-represented to the prejudice of the smaller ones and of the provincial schools as at present, will be the main guides to a fair and judicious choice, and, so far as the anatomical portion of the Board is concerned, everyone will probably be satisfied. But with regard to the Examiners in Physiology the position is quite different. Most of those who will probably be selected for their anatomical knowledge have no special acquaintance with modern physiology, and in this respect their election will not make the new Board any stronger than the old one. There are only five candidates out of the twenty-one who profess to have taught, or who are teaching physiology, and among these there is no name of any teacher of eminence in that science, or of anyone who has qualified himself for such a post by any experience as an examiner elsewhere. In fact, the present Court of Examiners comprises two excellent physiologists in Messrs. MARSHALL and SAVORY, and it will be quite impossible to make the new Board as strong in this respect by any selection whatever from the present list of candidates. The reason is not far to seek. Most of the physiological teaching in the Medical Schools, not only of the metropolis, but throughout Great Britain, has been and is being done by physicians. The restriction of the new Board to Fellows of the College, although in accord with the conservatism of Lincoln's Inn, is evidently fatal to the scheme, which is otherwise a most satisfactory one. The only Fellows of the College who have been appointed examiners in physiology at the London University in recent years are Messrs. SAVORY and POWER, and the new Board will apparently not secure the services of either of these gentlemen. If the selection be made from the published list of candidates only, as much dissatisfaction as at present, or even greater, is sure to prevail among those who present themselves for examination, especially at the Primary Fellowship, where a full and accurate knowledge of the present state of physiological science should be a *sine quâ non* on the part of anyone who is placed in so responsible a position as that of examiner therein.

As we have already suggested, it is highly desirable that at least two gentlemen should be appointed to examine in Physiology only; and unless this be done it is certain that the new regulations will have the effect of making the necessity for a Conjoint Board of Examiners the more apparent.

DR. FRANKLAND reports that, owing to the heavy floods, the river water during November was polluted with "large quantities of suspended impurities and of soluble organic matter of brown colour." The five water companies drawing their supplies from the Thames delivered throughout the month water which was quite unfit for domestic use even after efficient filtration. The Grand Junction water gave a deposit consisting mainly of matted fungoid fibres. The Kent Company's water was, as usual, good and palatable.

Annotations.

"Ne quid nimis."

OVERWORK AT SCHOOLS.

Since competitive examinations have been regarded as affording the surest test of individual capacity, they have multiplied in all directions, and increased in severity. And as, in England at least, a reputation once made is rarely lost except through grave delinquency or manifest failure of power, we cannot be surprised that every endeavour should be made to attain, at as early a period as possible, the success by which future position is to be secured. Formerly, when competition was limited to the struggle for a college scholarship or a place in the university class-list, and the army, navy, civil service, and East India Company's appointments were only to be obtained by interest, schools were selected on different principles than are now recognised: we are speaking rather of private than public schools. Then more regard was paid to the plan and method of education, and almost every school possessed in this respect an individuality of its own. At the present time the object of education appears less a matter of steady training and the patient laying of solid foundations, than a system of successful cramming, and a school seeks for reputation more in the number of public prizes annually won by its scholars than for the soundness of its scholarship. We do not intend, however, on the present occasion to enter into a discussion of the general merits or demerits of the competitive system, but simply confine our remarks to its effect on school work.

For a considerable period after the first introduction of the competitive system the great public schools made no effort to extend their system of education. Consequently large proprietary colleges, such as Marlborough and Cheltenham, were founded in order to meet the new requirements. These establishments differed only from the public schools in affording facilities for the study of the extended range of subjects required for the public competitive examinations, the traditions and method of the older schools being, however, still closely adhered to. The success and popularity attending these proprietary colleges led to the establishment of others, though not on such a sound basis, and the multiplication of so many institutions, all struggling for fame and existence, has led, we fear, to the introduction of a very unsound system of teaching. The smaller and later founded establishments, not possessing the *prestige* or reputation of the older schools, have sought to compensate for these deficiencies in increased efforts to secure success at examinations by putting increased pressure on the boys under their charge; and in order to get lads of special promise into these establishments, inducements are offered in the shape of scholarships or reduced terms—baits too eagerly swallowed by parents of straitened means. We have examined the prospectuses of many of these schools, and we have generally found the hours of work to be excessive, ranging from forty-five to forty-eight hours a week, which give a daily average on four whole school days of eight to nine hours, and six hours and a half on two half-holidays; this calculation does not include the Sunday school-work, which may be fairly reckoned as three additional hours. Eight hours a day of mental work is a considerable strain even for an adult; how much more for mere children, who have also to expend so much force to meet the vital requirements of the growing frame. Moreover, in adult life, the work, being more mechanical, is accomplished with less intellectual excitement than is the case where fresh facts and new ideas are constantly being acquired. If the pressure came at the later period of school life, and was permitted only for a few months immediately previous to an examination, we should perhaps have little cause to complain; but, unfortunately, the whole school career is one prolonged struggle. We cannot but regard the establishment of entrance scholarships at schools as a great evil, and as a most injurious extension of the competitive system. So long as the examination and the class-list closed the school career little mischief might be done, and time afforded for deliberate and sound study; but how can that be possible when before the boy is well out of the nursery he is put in harness, and driven along certain grooves in order to snatch a premature success which if attained only commits him more firmly to the grinding system. The world is acquainted only with the brilliant and successful side of the present system. It sees duly advertised in the public press that at Mr. So-and-So's school so many candidates have passed into the Civil Service or the Army, or have gained cadetships at Woolwich, and it does not stop to inquire at what expense these triumphs have been won. How many have broken down in the training, and how many have been hopelessly discouraged? Much of the responsibility rests with the parents who countenance this practice, and who do not see that this untimely forcing can only in the end yield a sickly and feeble fruit. Parents who do not wish their sons to be sacrificed to the Moloch of "early success" should jealously scrutinise the prospectuses of the schools to which they send their boys, and if the working hours are found to be excessive, the school should be avoided. As a general rule it may be stated that thirty-five hours of school work a week for boys under fourteen, and forty-two hours for boys above that age, is as much as the health and strength can fairly stand; whilst the success that still attends the old public schools, who rarely exceed these hours, shows that they are amply sufficient for educational purposes.

MILITARY MIDWIVES.

A correspondent has lately called attention to a subject which, on the ground of humanity if on no other, deserves consideration—namely, the provision of properly qualified midwives for attendance on the wives of soldiers as a substitute for those women who, without the rudiments of the art they profess, are permitted to call themselves midwives, and practise in barracks. Our correspondent's communication has special reference apparently to the case of the Royal Marine Artillery, which is, we are informed, under the Admiralty, and not the War Office; but it is unquestionably the duty of the authorities, whether naval or military, to ensure that the lives and safety of soldiers' wives be not jeopardised in their confinements. A number of properly trained midwives should always be available to meet the requirements of a garrison or regiment as the case may be. Since Lord Herbert's time considerable efforts have been made to secure something like decency and comfort for unfortunate women under such circumstances by the erection of a number of small lying-in hospitals at military stations, and these have been to a certain extent utilised for educating women to become nurses. But the great and prominent worker in this direction has been Dr. E. B. Sinclair, King's Professor of Midwifery in the School of Physic in Ireland, Trinity College, Dublin. Dr. Sinclair, having once served as a medical officer of the Royal Scots, no doubt had his attention forcibly directed to this great want, and it falls to the lot of very few men to have achieved a larger amount of practical good than he has done. He may claim to be considered a public benefactor as far as the army is concerned, for from 1869, when a school for training army midwives was formed in connexion with Sir P. Dun's Hospital, to the present time, he has sent no less than 271 well-trained midwives and ladies' nursetenders for service in the army. From the prospectus of this institution we gather that the course of instruction is ample, practical, and excellent of its kind, and that it is open to the wives of soldiers and non-commissioned officers to obtain their education free of expense. We notice that it is under the direct patronage of Her Majesty, and with the sanction of His Royal Highness at the head of the army, and we are led to wonder whether any other recognition of Dr. Sinclair's services has been vouchsafed him than the privilege of using the names of Royal personages as patrons of his good work.

THE LOCAL GOVERNMENT BOARD: COMPULSORY LOCAL HEALTH SELF-GOVERNMENT.

THE capacity of the Local Government Board in muddling the most straightforward matters amounts almost to genius. We have now some more definite details of the course it is taking in bringing into force the 286th section of the Public Health Act, 1875. This section gives the Board powers to combine districts for appointing a medical officer of health. When this section first appeared in the Bill, we pointed out that it was an unmistakable confession of failure of Mr. Stansfeld's so-called "policy" in one of its most important details; and when it passed through the House of Commons with the approval of Mr. Stansfeld—at least with no expressed dissent from him—we commented upon its irreconcileability with that "local health self-government" which he had vaunted, and which Mr. Sclater-Booth accepted as his aim and end. Mr. A. Doyle, one of the general inspectors of the Board, who had the privilege of first illustrating the muddle of the Board's administration of the Public Health Act of 1872, has apparently been conceded a like privilege with regard to the Act of 1875. He was at Wrexham the other day, bent upon a project of combining the counties of Denbigh and Flint into a single district for a medical officer of health, and this was his process of inducing the several sanitary authorities to assent to this combination. First, he told them that when, in 1873, he had submitted a like project to them, which had been rejected, he foresaw that the choice would be taken from them. This had been accomplished by the Act of 1875, and they were now in this position that their assent to combination was quite immaterial, for the Local Government Board were quite prepared to carry out such projects of combination as it might think fit to adopt on the recommendation of its general inspectors. When it was not unnaturally asked why he then consulted the sanitary authorities on the subject, and gave them the trouble of meeting to confer upon a question they had no control over, he curtly replied that if he hadn't done so he would have been held discourteous, and that the Local Government Board would prefer having their assent to its action, although it was determined to act without it (the politeness of the headsman before decapitating his victim). If they thought fit to kick they might do so, but he warned them that it would be a useless and expensive process, involving much legal trouble, and would benefit nobody but the lawyers engaged. Speaking to a Committee of the Wrexham Town Council, Mr. Doyle is reported to have said: "'Must' was the last word he liked to use in the presence of gentlemen connected with local administration, but 'must' was the only word that would suit this case." This is "local health self-government" with a vengeance.

But this is, after all, the least, although locally the most aggravating, part of the business. Mr. Doyle told the Wrexham Town Council that the Local Government Board would in due time issue an order defining the duties of medical officers of health for large combined districts; also the duties of such assistant medical officers who might be appointed within these districts. We have more than once pointed out that the existing regulations of the Local Government Board as to the duties of medical officers of health were treated as a dead letter by the general inspectors of the Board. But here we have the Board urging the formation of districts for the appointment of officers, and requiring the assent of local authorities to them, the duties to be performed in these districts not having yet been made known or determined upon! The Board itself affects to judge of, and requires the approval of local authorities to, an organisation the fitness of which can only be determined by a knowledge of the duties for which it is made, but of which the duties are not yet known. This the general inspectors of the Board designate a policy of common sense. A course like this, which must postpone a sound local health sanitary administration indefinitely, can only be expected to be successful by its audacity.

The Wrexham Town Council has refused to be brow-beaten by the Local Government Board, and has determined to oppose the combination of the two counties. It is absurd to suppose, Mr. Doyle notwithstanding, that a court of law or Parliament would ratify a compulsory order of the Board for an organisation, the purposes of which the Board itself has not defined by setting forth the duties of the medical officers of health, which would be preposterous in view of the existing regulations as to such duties, and which, until these duties be defined, cannot be rationally discussed.

SEASONABLE WEATHER.

THERE are some people who hail the appearance of what is termed seasonable weather as a source of congratulation, and pride themselves on taking brisk exercise in all weathers, and never coddling. And, no doubt, to a man who can take his cold bath every morning with a relish (he has, perhaps, a fire in his dressing-room), who can eat a hearty breakfast (and has a good breakfast to eat), and start off in his Ulster, the present weather is not so disagreeable. It rouses him to take active exercise, sharpens his appetite, and, as he says, "pulls him together." But there is another way of looking at the weather, and it is the way, unfortunately, that most people have to regard it. An old officer, after dining at his club and sitting by his club-room fire, turns out into the street and meets a keen north-east wind; if his pulmonary and circulatory organs are not in fine working order, he contracts a bronchitis, and a rapid congestion of the lungs soon gives rise to that promotion which his juniors had almost despaired of from his having so long blocked the way. Or an individual who has long lived "regularly but well, Sir,"—that is, he has lived a trifle too well—finds that the same wind suddenly checks the action of his skin, and his liver or kidneys, which had already been working at high pressure, do not accommodate themselves to the extra amount of duty suddenly thrown upon them, and an attack of gout or sciatica is the result. The snow-sodden boots of children and the keen frosty air speedily develop chilblains; and the biting wind is a terrible test to everyone's weak places. The physician endeavours with infinite pains, and by the aid of his various appliances, to elicit information as to the nature and seat of his patient's disorder, but this weather soon makes manifest the weak and vulnerable places in a patient's system. The hitherto latent affection of a lung is suddenly developed into activity, and the north-east wind finds out the stopping in a tooth, or searches out the ends of all the nerves at all disposed to neuralgia, and it causes the benumbed and chilblained fingers of the pianist to lose their cunning. Your dark olive-complexioned man, regular at his desk in the city, but irregular as to exercise outside his office, finds himself suffering from a violent bilious attack attended with shivering, nausea, headache, and loss of appetite, and has to wrench himself from that desk to which habit has so long chained him, and about which he has boasted that he was "always to be found there at his work, Sir." If such be the evils to which the rich and well-to-do are exposed, what must be the sufferings and privations of the poor! If anyone will only attempt to realise what it is never to feel warm—and there are many poor women, and very old and young persons especially, who never know what it is to be warm,—he will have some idea of what the poorer classes undergo during the seasonable weather of which we have been tasting a specimen. When they become ill the hospital or the workhouse is open to them, and they look forward perchance to death as to a prospect of relief from physical suffering at any rate. Seasonable weather is a melancholy practical application of the Darwinian dogma; the fittest only survive in that terrible struggle for existence through which so many have to pass during the rigours of an English winter.

A COUNTY COURT JUDGE ON MEDICAL CHARGES TO WORKING MEN.

Judge Smith, of the Hereford County Court, has the merit of decided views on the subject of medical charges to working men. A case came before him the other day in which Mr. Thomas Mason, surgeon, of Wellington, Hereford, preferred a claim against William Woodhouse, of the same village, for professional attendance on Woodhouse's family, affected with fever, living two miles away. His charge was 3*s.* 6*d.* a visit. The whole sum claimed was £12 15*s.*, which included a charge of 7*s.* interest. The defendant admitted owing the sum of £11, but disputed the balance. Three and sixpence a visit, his Honour said, was too large, especially in the case of an ordinary labouring man, and he could not allow more than half-a-crown. He had one rule for medical men which he always laid down. It was this. A doctor was entitled to a minimum charge per visit of half-a-crown. If the visit had to be made to a distance the charge would be 1*s.* per mile inclusive. For instance, if a medical man had to go ten miles he would be entitled to 10*s.*; if he went five miles he would be entitled to 5*s.*, and so on. The minimum would, however, always be half-a-crown. Mr. W. Boycott, who appeared on behalf of the plaintiff, pointed out that at each visit where he had charged 3*s.* 6*d.* Mr. Mason had been obliged to drive two miles. Was he entitled to half-a-crown only for such service? His Honour replied that had he not fixed a minimum of 2*s* 6*d.*, Mr. Mason would only be entitled to 2*s.* The plaintiff said it would be impossible to work for such a sum. The prices of everything had risen so much that a medical man could not possibly support himself with such charges. His Honour replied that he could not allow more, and that the present bill must be taxed by the registrar and reduced by the scale he had named. When this had been done judgment would be given for the amount.

The Judge's view of a minimum charge is not to be complained of; but it is strange that, with so just a basis of reasoning, he should come to such a lame conclusion. In his judgment he makes no allowance for the three elements of *distance, more than one patient, grave and infectious character of cases.* We will not say that 2*s.* 6*d.* per visit might not be a sufficient allowance for the judge to sanction, but we are bound to say that it could be no adequate remuneration to the medical man, and that nothing could justify such a low allowance in the circumstances but the inability of the defendant to pay more, which was not proved or even alleged.

THE CASE OF SURGEON SPURWAY, LATE OF H.M. ARMY.

We have received a copy of the correspondence that took place between the head of the Army Medical Department and Mr. Spurway whilst in that branch of the service, in reference to the latter officer having been gazetted on half pay without half pay for a period of six months. Indignant at this proceeding on the part of the War Office, Surgeon Spurway very naturally took the further step of declining to hold her Majesty's commission under such circumstances, and accordingly sent in his resignation, which was accepted. The facts of the case, as contained in the document before us, have already received a good deal of attention and discussion, and may therefore be assumed as pretty well known. It is not disputed that Surgeon Spurway had served as a medical officer for ten years, during all of which time he had maintained an unblemished reputation; that he returned from India in consequence of an affection which, if not induced by that climate, was nevertheless aggravated by it, and that he was at the end of six months' sick leave officially informed that, there being no regulation under which he could be granted half pay, because his disability was not contracted *in* and *by* his service, it had been determined to place him on the half pay list for six months, but *without half pay.* It is, moreover, not denied that officers who have left the service on account of misconduct have been granted a reduced or temporary rate of half pay under the clause of a Warrant which is declared to be inapplicable to Surgeon Spurway's case, although it would certainly appear to anyone reading it to have been expressly drawn up to cover all those cases not provided for by a previous clause in the same Warrant. If the copy of the communications before us embody all the facts that are really relevant to the case, and if Mr. Spurway can substantiate the position he has taken up in his communications—for we need scarcely add that all turns on this,—he has a strong case against "the authorities," be they who they may; and as this matter of half pay without half pay must affect other officers besides Mr. Spurway, we would advise him to get the subject taken up in the House, in order that we may know who is answerable for the course that has been taken, and, in fact, all about this matter; and it might be well to be informed at the same time how it is that regulations are drawn up so as to express what is not intended, and conceal what is.

THE HARVEIAN LECTURES.

The first Harveian lecture at this Society was delivered by Dr. Sibson on the 2nd inst., when, in spite of the inclement weather, a large audience assembled. Taking for his subject "Bright's Disease and its Treatment, considered mainly in relation with Arterial Tension from Blood-contamination," the lecturer in the first place dwelt at considerable length upon the results obtained by the post-mortem examination of 277 cases of Bright's disease, with special reference to the size of the heart. From this analysis he drew the following broad conclusions. That in the large majority of cases of renal disease, whether acute or chronic, there is enlargement of the heart, chiefly hypertrophy of the left ventricle. That the degree of enlargement varies according as the disease is associated with other wasting affections, in which case the organ is found to be of natural size, or even small. Thus, in 9 cases of acute Bright's disease (non-scarlatinal) the heart was small in no case, of natural size in 2, both of which were associated with wasting disease; rather large in 3, and very large in 4. In 5 scarlatinal cases 2 presented hearts of the normal size, and in 3 the heart was rather large; but of 54 examples of the large white kidney in 15 the heart was small, 13 of the cases being associated with wasting disease; in 17 the organ was of natural size, 12 being associated with wasting disease; in 8 the organ was rather large, and in 14 much enlarged. Of 106 examples of the contracted kidney, the heart was small in 4, all being associated with wasting diseases; of natural size in 25, 18 being combined with wasting disease; in 20 it was large, and in 60, or 56 per cent., greatly enlarged, and this although in 21 of the cases there was wasting disease or emaciation. He adduced other facts on the same head, into which we cannot enter now, and pointed out the effect of arterial degeneration in modifying these results. Turning to the clinical evidences of arterial tension, Dr. Sibson enumerated the characters of the pulse, the evidences of enlargement of the aorta, and the presence of reduplication of the second or of the first cardiac sounds; the former heard over the conus arteriosus, and the latter over the ventricular septum; and he related some striking examples of these signs, most of which are present even in acute cases. In fact, in the acute cases the signs of arterial tension are better marked and of more certain value than in chronic cases where other influences come into play. Dr. Sibson proposed to leave the consideration of the sphygmographic tracings of the pulse, and the bearing which these facts had on the treatment of the disease, to the second lecture, which was announced to take place on the 9th inst.

SANITARY MEMORIALS OF MILLBANK.

As the vast prison that adorns the northern bank of the Thames, near Vauxhall Bridge, is shortly to be demolished, we may fitly recall to the notice of our readers the sanitary experiences that have been gleaned within its walls. The building was erected in 1812–16, and the site is described as about the worst that could have been selected, the neighbourhood being marshy and the soil a quagmire. The foundations were consequently so insecure that, shortly after the establishment was opened, three of the angle towers sank and sealed up the passages, so that the warders could not open the doors. Six years after it was found that the general health of the prisoners began to decline, and in 1823 what is known in prison statistics as the great epidemic made its appearance. This epidemic consisted of a severe and widespread outbreak of scurvy, followed by a most obstinate form of dysenteric diarrhœa. Spongy gums, ecchymosed and blotched legs appeared, and before long half the prisoners were affected, the women being more severely attacked than the men. Some few, however, were entirely exempt, and notably those employed in the kitchens, while it was found that among the staff of officers, who with their families numbered 106 persons, not one was affected. Soon after the commencement of the outbreak Dr. Roget and Dr. Latham were consulted respecting the nature of the disease. It was speedily found that, owing to some severe Parliamentary criticisms as to the extravagant and "fattening" scale of diet in vogue, a crucial and, as it proved, a most unhappy reform was effected. Solid animal food was entirely excluded from the scale, the bread was reduced, and no potatoes were given. This evident exciting cause of the outbreak was probably aggravated by cold, for those who occupied the coldest cells suffered most. The diet was changed, meat, vegetables, and oranges were given, and the patients lost their scorbutic and also the diarrhœa. But in the summer of 1823 dysenteric diarrhœa again appeared, and affected officers, servants, and all alike. It was found, by reference to the apothecary's books, that chalk-mixture and laudanum had been frequently prescribed for some time previously. The ordinary astringents, however, in this outbreak were unsuccessful, and, after a partial success with mercury and some other remedies, it was decided to empty the prison. In May, June, and July of the year above quoted, the number of cases on the sick-list rose to 454 out of a prison population of 800 persons, and 30 deaths occurred. The prisoners were removed to the Royal Ophthalmic Hospital, then in Regent's-park, and to the hulks off Woolwich, and all quickly regained their health, though it appeared that the Woolwich detachment convalesced more rapidly than the others, whereas the few left at Millbank for some short time showed no improvement. It was therefore resolved to confer a free pardon on the female prisoners, and transfer all the men to the Woolwich hulks. This was done, the disease quickly disappeared, and after a few months the prison was re-occupied. Some years ago a slight outbreak of scurvy again occurred, but, with this exception, the prisoners have been maintained in a fair average state of health. Many other particulars of the great epidemic may be found in a Blue Book on the subject, published in 1823, in Latham on the "Diseases of the Penitentiary," and in "Memorials of Millbank," a very interesting book that has recently appeared from the pen of Captain Arthur Griffiths, deputy-governor of the prison.

WESTMINSTER HOSPITAL.

The long-talked-of improvements in the sanitary condition of this hospital have at length assumed a definite form. On the 16th of March last, a sub-committee, consisting of Sir Rutherford Alcock (as chairman), Dr. Basham, Mr. Brooke, Mr. Cowell, Mr. Richard Davy, Dr. Dupré, Dean Stanley, Mr. Charles Hood, Mr. Helmore, and Mr. W. Gilbert, was appointed to consider the whole question. This committee has, with the valuable assistance of Mr. Hunt, C.B., and of Mr. Stephen Salter, as architect, recently presented a full and exhaustive report, which was accepted on Tuesday last by the House Committee, and referred to a general board of the governors in January next for final consideration.

The recommendations of the sub-committee are briefly as follows:—The addition of octagon towers in front and angle buildings behind, by which the whole of the sculleries and waterclosets will be placed outside the building, with a connecting lobby entered from the several wards and cross ventilated; the addition of consultation and retiring rooms to the operation theatre; the erection externally, so as to be entered from each ward corridor, of bath and lavatory rooms; the addition of a new floor to part of the building, to provide wards for the accommodation of infectious and delirious patients; a complete system of ventilation by perpendicular tubes in each ward; besides many other improvements, such as alterations in the out-patient department, painting and colouring the hospital throughout, improving the mortuary, &c. These important alterations are estimated to cost nearly £8000, and will, it is hoped, be carried out next summer. The towers and buildings outside can be constructed first, so that the hospital will not require to be closed for more than six or eight weeks.

THE PRINCE'S TOUR IN INDIA.

The detailed accounts of the doings of His Royal Highness at Bombay, of which the telegraph had already briefly apprised us, have since reached this country. While it belongs to other journals to describe the splendour and variety of the scene which the city of Bombay presented, and to chronicle the vast political influence which the Prince's visit may exercise over the future history of India, we have to congratulate the nation on having so little to say in our pages from a medical standpoint. Monotony is not ordinarily the source of gratification that it is in the present instance. Our written intelligence, transmitted by the mail which left Bombay soon after the arrival of the Prince of Wales there, carries our previous information of the voyage of the *Serapis* onwards from Aden to Bombay, and it is to the effect that the Prince and all on board were well; indeed, to employ nautical phraseology, there was a clean bill of health, no one belonging to the Prince's suite being on the sick list. The *Serapis* made an excellent passage from Aden. It became cooler out of the Gulf of Aden, the thermometer falling to 78°, 80° F., with a pleasant N.E. breeze, which continued all the way; but the heat became greater at Bombay, being 82° and 83° F. on the 8th ult. The Prince was in remarkably good health and spirits, and, according to the then existing programme, His Royal Highness was to remain in Bombay until the 17th, when it was intended to proceed to the south to Beypore. The shooting expedition to the Annamully hills had not been finally settled, but depended upon the receipt of positive assurances as to the freedom of those parts from disease. Apparently nothing could have been more prosperous than the Prince's tour so far. His Royal Highness's public reception at Bombay was a most magnificent spectacle, and as far as human foresight and medical experience are concerned, the nation may confidently expect the Prince to be protected from all avoidable risks to health until the time of his return, when we anticipate seeing His Royal Highness all the better for his Eastern tour.

THE REGISTRAR-GENERAL'S HOSPITAL STATISTICS OF SCARLET FEVER.

STATISTICS are valuable in proportion as they are correct. To be able to decide upon the value of statistics requires a knowledge of facts, and of how to use them. Therefore, it is a favourite device of those who do not possess these qualifications to lose no opportunity for disparaging the value of statistics. The Registrar-General recently published some statistics upon the mortality of scarlet fever cases in the Metropolitan Asylums Board hospitals, which were full of interest, as the treatment of this disease on a large scale in hospital is more or less an experiment, the result of which has an important bearing upon the influence of hospitals for controlling infectious diseases. At a recent meeting of the managers of the Asylum District, Mr. Shaw Stewart unfortunately remarked that "he had no knowledge of where the Registrar-General might have got his figures, but he was prepared to say they were not correct." *Apropos* of this remark, our contemporary the *Pall Mall Gazette*, in a sham panegyric on the value of statistics, remarked that "they have the immense advantage over common sense and experience that they are capable of adjustment to almost any extent." It undoubtedly requires a large share of common sense to estimate the value of statistics, which are, after all, little more than tabulated experience; but it is difficult to see how mere common sense is to decide on such points as the value of hospital treatment for stamping-out scarlet fever. As to the point in dispute between Mr. Shaw Stewart and the Registrar-General, it appears somewhat remarkable that Mr. Shaw Stewart should have had any doubt as to the source of the Registrar-General's figures, since that official has from the beginning of the year been regularly supplied by the managers of the Asylum District Hospitals with copies of the weekly returns furnished by the medical officers of the institutions. Uninformed as to the source of the Registrar-General's figures, it is only reasonable to suppose that Mr. Shaw Stewart is mistaken in supposing that they are incorrect. Indeed, returns since published by the managers relate to the mortality of all patients in the Asylum District Hospitals in the six months ending September, whereas the Registrar-General's figures related to scarlet fever alone during the first nine months of this year. This is probably the explanation of Mr. Shaw Stewart's blunder.

THE LAST APPOINTMENT TO A CORONERSHIP.

DIFFERENT people entertain different opinions as to the qualifications requisite for a coroner. A legal training is held by some, just as a medical training is held by others, including ourselves, to be the best qualification for that office; but the electors in Suffolk have taken their own view of this matter, and a very original one it is, we must say. They have elected an auctioneer as their county coroner! And it was not that the electors were restricted in their choice by the limited number of candidates for the office; for at least one member of the medical and two or three of the legal profession, one of the latter being the deputy coroner, were among the candidates. The election seems to have been of a purely political character, and Mr. Chaston (the auctioneer) at a very early stage of his canvass is stated to have secured the support of several persons of influence among the county Conservatives. The use of an auctioneer's rostrum and hammer, and familiarity with the best methods of inducing people to bid for lots in an auction-room, would not appear to most people the best training for a judicial office; but the electors of Suffolk thought otherwise. The result of this election would be ludicrous were it not lamentable; and we are reluctantly compelled to inquire whether the time has not come for remodeling the system by which coroners are elected. It would be infinitely preferable to make the Lord Chancellor responsible for nominating coroners than to have their election sink into an affair of party politics, with all the concomitants of canvassing, cabs, committee-rooms, and placards.

THE DRAINAGE OF LINCOLN.

THE Corporation of Lincoln have received a notice from their engineer, Mr. Mansergh, demanding a settlement of his account for work done in preparing schemes of drainage for the town. "If," says Mr. Mansergh, "the Council intends to set the Local Government Board at defiance, and the carrying out the works is to be indefinitely postponed, I shall request to have a payment made on account of what has already been done; or if they prefer to employ some other engineer they are quite at liberty to do so on *the settlement of my account*." Mr. Mansergh writes thus plainly because he thinks "after nine years' delay, it is time some decision should be arrived at, and that he should be assured, so far as he is concerned, that the matter is either to proceed or be dropped." Mr. Mansergh's letter seems to have caused some consternation and surprise amongst the members of the corporation, but after discussion it was decided "that Mr. Mansergh be requested to send plans, sections, detailed drawings, specifications and estimates, and draft contracts for the proposed works of sewers and sewage disposal, in order that they may be investigated by the Council prior to tenders being invited; the Council being of opinion that they would not be justified in committing their constituents to so large an expenditure as that involved in carrying out the proposed works without the fullest previous investigation." In this resolution we have an instance of the craft which has enabled this "ancient municipality" to set at defiance, for so long, the mandates of Gwydyr House. The corporation have already spent nine years in making "previous investigations" with respect to drainage schemes; and in asking more time for a consideration of Mr. Mansergh's estimate, which has been before them since Oct. 2nd, 1873! they are only repeating the tactics which have been so successful with the Local Government Board. We prophesy, unless

Mr. Mansergh presses his point with firmness, that the settlement of his account, and the plans for the town drainage, will both be "indefinitely postponed."

MICRO-PHOTOGRAPHY.

There can be no doubt that histological advances are considerably hampered by the necessity of having the microscopical characters drawn by the observer himself. He can only convey upon paper the impression that he has formed of the object, and however faithful may be his representation, it must necessarily lack completeness. The application of photography to the microscope obviates this difficulty, but only to raise others equally objectionable. The photograph is too faithful a representation, and too often results in a blurred and confused picture. Dr. Luys, who has for some time devoted himself to the subject, in the current number of Brown-Séquard's *Archives*, advocates the use of this method, and illustrates his paper by a photograph prepared by a new process of a section of the cortical matter of the cerebrum. But we are bound to say that the specimen thus given does not appear to us to aid the histologist. At the last meeting of the Medical Microscopical Society (which, by the way, is by no means so well attended as it should be), Mr. G. Giles gave a clear and interesting description of the means he has adopted to ensure good results in micro-photography. We need not here enter into a full description of his apparatus, except to mention that it is so arranged that the camera is directly connected with the microscope, the light being thrown on the object by means of a three-inch condensor, with ten inches focal length. Mr. Giles showed a large number of photographs of histological (normal and morbid) specimens, some of which were certainly most excellent representations. As Mr. Giles stated, the great difficulty lies in the fact that in the photograph only those parts of the field that are precisely in focus come out clearly, so that in every picture parts of the object are less distinct than others. But it is possible that this difficulty may be overcome, and we hope that Mr. Giles will continue his efforts in this direction. Simplicity and rapidity are, of course, very essential points, and if these be attained much labour will be saved, and great accuracy in histological research ensured.

FEVER IN ROME.

The health of Rome during the winter is a subject not entirely without interest in this country, especially to the migratory English who are able and glad to select for winter residence a more congenial climate than it is possible to enjoy in this island. According to official returns published by the Registrar-General, it appears that the annual death-rate in Rome during the six weeks ending 14th November, was equal to 37 per 1000, against 23 in London. The Roman death-rate, it is true, is reduced to 32 per 1000, by the omission of 183 deaths in the returns from that city during the six weeks, which are described as of strangers or non-residents; no such correction, however, is made in the London returns, which undoubtedly include many deaths of non-residents, as it is estimated by the Registrar-General that these deaths are more than balanced by the deaths of London residents occurring outside its boundaries. The principal feature of the recent Roman returns has been a marked increase in the fatal cases of fever, which, during the six weeks under notice, have numbered no less than 220, equal to an annual death-rate of 7·5 per 1000; whereas the fever-rate in London in the same period (exclusive of scarlet fever) did not exceed 0·4 per 1000; in other words, fever was nineteen times as fatal in Rome as in London. During the last of these six weeks the deaths referred to fever in Rome were 52, a considerably higher number than in any previous week this year, and included 29 described as "eruptive," 10 as "febbre d'assorbimento," 7 as intermittent, and 6 as typhoid. The term "eruptive fever," which includes the largest proportion of the total fever deaths, is far too indefinite to afford a satisfactory clue to the type of this fatal form of fever; neither is "febbre d'assorbimento" much more instructive. The death-rate from fever is, however, undoubtedly high, and, combined with the excessive rate from all causes, affords further conclusive evidence, were it necessary, of the unsatisfactory sanitary condition of Rome.

THE IMPERIAL BOARD OF HEALTH IN GERMANY.

A sum of £800 has been put aside in the German Chancellor's budget for the establishment of a Supreme Board of Health for the empire. Judging from this small sum, the organisation cannot become a very extensive one. Its principal object will be to collect reliable statistics in sanitary matters, though there are hints that the new board will be a sort of sanitary court of appeal to which the district administrative boards or provincial governments will have to refer for sanitary advice and decision, so that immediate action would have to be taken after its judgment. In semi-official correspondence, the name of Dr. Struck, Prince Bismark's body physician, has been put forward as the future president of this new board, which is to be placed under the immediate control of the Chancellor, without an intermediate State Ministry. Dr. Struck was a private physician at Frankfort during Prince Bismark's stay in that city as envoy for the old German Confederation. He entered the army in 1866, was transferred to a regiment at Berlin, and is at present the regimental Oberstabsarzt of the first Grenadiers of the Guards.

THE LATE RIGHT HON. T. E. HEADLAM.

We regret to announce the death of the late Mr. Headlam, the ex-member for Newcastle-on-Tyne, very honourably associated with the last successful medical legislation—that of 1858. We are indebted for the Medical Act to him and to Mr. Walpole, more than to any other two public men. It is neither unreasonable nor detracts from Mr. Headlam to suppose that for some of his ability to cope with this subject he was indebted to his uncle, the late well-known Dr. Headlam, of Newcastle-on-Tyne. Mr. Headlam continued until lately to feel an interest in the Medical Acts and their amendment, though his paternal feelings towards the Act of 1858 made him view with some jealousy other and more thorough measures of reform. This is little more than we should expect. A finality feeling takes possession of the best reformers. But this should not hinder us from doing justice to their contributions of help to a good cause, though we may not regard them as conclusive ones.

THE MARRIED SOLDIER IN INDIA.

The married soldier is, as a rule, much better off in India than at home, and were it not for the loss of health which residence in a tropical climate entails on women and children, Indian service would for them also be far preferable. Of late years efforts have been made, no doubt, to improve the condition of the soldier in every way, but the soldier's family very often fares badly on home service. The Government of India laid down a scale of accommodation for married soldiers in 1864, by which each of them was provided with two rooms, one measuring 16 by 14 ft., the other 14 by 10 ft. This scale was fixed mainly with reference to quarters in the plains. According to the late Report of

Sanitary Measures in India, the accommodation for hill-stations has since been considered, and provision has moreover been made to some extent to adapt the size of the rooms to the requirements of large and small families. Each set of quarters is to have a bath-room attached, and the floor of the buildings is always to be raised one foot at least from the ground. We learn from the same Report that the statistics of sickness and mortality among soldiers' wives throughout India in 1873 presented a very favourable contrast to those of the previous year; and the children of European soldiers also suffered much less than usual during 1873. These favourable results do not seem, however, to be attributable to any general or special sanitary improvements, but to the fact that the year under report was an exceptionally healthy one in India.

DEATH FROM CHLOROFORM.

A RECENT death from chloroform in the practice of Mr. Chesshire, one of the surgeons of the Birmingham Eye Hospital, presents some peculiar features. The patient was a gardener, forty-two years of age, who had received a gun-shot wound in his right eye while beating for game on the 16th ultimo. The safety of the other eye being endangered, Mr. Chesshire recommended extirpation of the affected eyeball. Forty or fifty drops of chloroform were administered on a towel, and the patient "immediately became semi-unconscious." The operation was commenced, but the patient not appearing to be sufficiently under the influence of chloroform, forty or fifty drops more were given. Mr. W. M. Jackson, of Smethwick, noticing a failure in the patient's pulse, at once seized him by the feet and lowered his head. He afterwards practised artificial respiration, but the man died in about half an hour from the time of the first administration of the chloroform. The patient had no disease of the heart, and was free from excitement prior to the operation. It is remarkable how small a quantity of chloroform proved fatal in this case; probably not more than two drachms were used altogether, and every precaution was taken in the administration of the drug, and yet death resulted.

THE CAUSE OF THE FEVER EPIDEMIC AT CROYDON.

WE hear that an important discovery has been made with reference to the causation of the remarkable epidemic of fever in Croydon, which, if not affording the true solution of the mystery, at any rate offers a most reasonable suggestion for its explanation. A huge waste-pipe from the water tower of the Croydon Waterworks has been found to have had direct communication with the sewer. It is needless to say that this connexion, which afforded the utmost facility for aerating the water supply with sewer gas previous to delivery, has been effectually secured. The recent weekly returns of the Registrar-General show a decrease in the deaths from fever in Croydon, and we hear locally that the number of cases has considerably decreased.

RESECTION OF THE KNEE.

AMONG the young French doctors who visit the hospitals of London, some endeavour to acquaint their countrymen with English modes of practice which have not penetrated fairly into France. M. Picard has just been very successful in that way, and has published a pamphlet which offers a faithful sketch of the rise and progress of resection of the knee. The paper is almost exhaustive, and full of details and statistics of the utmost value. M. Picard has attended the large hospitals, and witnessed the operations and practice of some of our leading surgeons. He renders full justice to the perseverance with which this form of resection is being applied, and shows that careful dressing is of importance in these cases. The author is a great admirer of Lister's plan of treating wounds, and his glowing description will certainly tend to a more general adoption of Prof. Lister's views amongst French surgeons. M. Picard was assisted in his labours by Mr. Howse, of Guy's Hospital, who seems to have been particularly successful in resection of the knee.

A HINT TO THE HARVEIAN SOCIETY.

AT a meeting of the Accademia Medica di Roma on the 7th November, the president, Professor Maggiorani, in acknowledging the gift of the work in which Dr. Ceradini, of Genoa, claims for Andrea Cesalpino the priority in discovering the circulation of the blood, suggested that a monument should be erected in the University, to commemorate the discovery and its author. Professor Baccelli seconded Professor Maggiorani, and contended that Cesalpino anticipated Harvey in conceiving and demonstrating the fact of the circulation. To an Italian, therefore, and a professor in the University of Rome, the greatest physiological discovery of modern times was due. We hope that the Harveian Society will not allow this "revendication" to pass without challenge, and that our great English physician will find an effective "apologist." Italy has substantiated her right to priority in the transfusion of blood; it is too much when she claims to have been the first to demonstrate its circulation!

ZYMOTIC DISEASE IN KEIGHLEY.

THE small-pox epidemic in Keighley has only died out to be replaced by a still more fatal epidemic of scarlet fever. During the four weeks ending 18th November the medical officer of health reported that 23 deaths resulted from scarlet fever, being equal to an annual rate of 11·5 per 1000 of the estimated population of the local board district. Scarlet fever caused 10 deaths in the district in the first quarter of this year, 36 in the second, 18 in the third, and 36 in the first half of the current quarter, making 100 since the beginning of the year. This exceptional fatality from scarlet fever is attributed by the medical officer of health to the defective sanitary condition of the town, two-thirds of the streets being practically undrained, and, according to a recent report, 71 of the streets were unpaved. The members of the Local Board seem to be more intent upon disputing the reports of their medical officer than upon redressing the undoubted evils with which the town abounds. The medical officer of health has made a claim for extra remuneration for his indefatigable and thankless services during the late severe small-pox epidemic, and the claim has been met by a paltry offer of £30 from the Local Board, which has not been accepted.

THE LAST THING IN THE WAY OF FORAGE ALLOWANCE.

AMONG the Army Circulars issued for the present month is one—clause 163—prescribing the conditions under which forage allowance is to be drawn for the future. These conditions are to come into force on the first day of the new year, and apply to combatant and non-combatant officers alike. In the first place, the horses of all officers whose duties require them to be permanently mounted must be *bonâ fide* their own property, to entitle them to forage allowance. One is tempted to pity the unfortunate officer whose duties require him to be permanently mounted in this weather. Still, it is tolerably clear what is intended by the term "permanently mounted," as contra-distinguished from the position of those officers whose duties require that they shall be temporarily or occasionally mounted. These latter can draw forage allowance—at least so we read the regulation—so long as they actually possess a horse or horses of their own, and their duties entitle or require them to be mounted; or they can "hire a hack" and charge the cost thereof to the public, supporting their claims by vouchers; but the expense so incurred must not exceed that to which they would be entitled as forage allowance for specified periods of time. Now, it strikes us that in these days, when horses are very dear, an officer might not care to purchase a horse to provide for the performance of duties which might only last so long as he held a particular post, when he would have to maintain his horse at his own expense, or sell it to purchase a new one when required. And if he has recourse to the hiring process, he had better assure his life before crossing the back of some livery-stable animal, and riding it for the first time in the immediate vicinity of artillery practice.

THE Local Government Board, which recently held an inquiry as to a proposed new source of water-supply in Richmond, have granted powers to the Select Vestry to construct works. In pursuance of their powers, the Vestry have purchased the Old Brewery, with its deep wells in the chalk, and have accepted contracts to the amount of £25,000 for the erection of the works. It appears that the Local Government Board, when the matter was under discussion, declined to express any opinion on the legal points of the case, and, in consequence, the Southwark and Vauxhall Company have given notice to the Vestry that they are applying for an injunction to restrain their proceeding further in their attempt to provide Richmond with a pure water-supply. The London water company will probably succeed in putting the Richmond Vestry to a considerable expense; we trust, however, that their effort to maintain their monopoly will fail.

AT a recent meeting of the executive committee of the British Pharmaceutical Conference, a suggestion was made that the Conference should nominate, in connexion with the Cambridge University Extension Scheme, a Travelling Professor of Pharmacy, with a stipend of £150 a year, whose duties would be to lecture in the provinces at different centres. After discussing the proposal the committee appeared unanimously of opinion that at present it would be unwise to include the subject of education among the objects of the Conference. For the thirteen years of the existence of the Conference these objects have been the prosecution of original research in connexion with pharmacy, by means of publications and money grants, and the holding of annual meetings of members for the reading and discussion of original papers and for friendly intercourse.

IN London last week 1628 deaths were registered, including 59 from measles, 104 from scarlet fever, 16 from diphtheria, 54 from whooping-cough, 29 from different forms of fever, and 13 from diarrhœa. No death from small-pox was recorded. The mortality from diseases of the respiratory organs, notwithstanding the inclement weather experienced, was below the corrected weekly average number. The death of a woman aged forty-four years was referred to "morphinism." On Saturday the London Fever Hospital contained 109 patients.

WE have received a copy of the "Smallest Bible in the World" from the Oxford University Press Warehouse, Paternoster-row. It is printed in very small, clear type, on unbleached India paper, measures barely half an inch in thickness, and weighs when bound in morocco less than three ounces and a half.

THE recent meeting of the American Public Health Association at Washington seems to have been a decided success. The inaugural address was delivered by Dr. Toner, who strongly urged a close imitation of the manner in which sanitary reform is worked out in England, which he politely termed "the most enlightened country in Europe." The meeting extended over four days, and drew together a large number of the more prominent members of the medical profession in the States. There were in all thirty-two papers read—rather a plethora of communications perhaps for an association in the third year of its existence. Among other matters it was decided to memorialise Congress to introduce a better system of registering births, marriages, and deaths. The Association has the good wishes of all sanitarians in this country.

A LINCOLNSHIRE paper announces that enteric fever of a most virulent character has broken out in the village of Appleby. In one house where the disease has raged there is only one sleeping room for a man and his wife and seven children; in another cottage, one room divided by a wooden partition contains a family of eleven. The state of the wells and the privies would appear to be disgusting. Yet the village is within a short distance of the residence of one of the members for North Lincolnshire. We hope the sad state of his poorer neighbours has been brought under the notice of this gentleman. Self-interest alone would dictate the eradication of a pest spot in such immediate contiguity to his dwelling.

IT is with regret that we have to announce the death of Mr. William Acton. On Monday last, Mr. Acton was in his usual health, and in the evening of that day entertained some friends at Harley-street. He retired about one o'clock, and at half-past eight on Tuesday morning had, as usual, a cup of chocolate in his bedroom and was then apparently quite well. As he did not appear at breakfast, about half-past nine o'clock someone was sent to call him, but found Mr. Acton lying across the bath dead. Dr. Garrod was called in, but life was extinct.

A PAPER was read before the Society of Arts last week by Dr. Richardson "On Industrial Pathology, or the Influence of certain Injurious Occupations on Health and Life." From researches which had been made, Dr. Richardson was enabled to state that the rate of mortality is greatest among the class of persons who traffic in intoxicating liquors, and the principal cause of degeneration of working men was alleged to be intemperance. The lecture, one of a series to be delivered during the winter, was distinguished by Dr. Richardson's usual ability and effective delivery.

AT the last monthly meeting of the Halifax Town Council, by the adoption of the minutes of the Sanitary Committee, it was resolved that the plant, live stock, carriages, tools, and implements of every description, belonging to the Goux Manure Company in Halifax, should be purchased for the sum of £3500. This sum, it was stated, included a licence to use the system for the future as well as existing closets in the borough. It is evident that the Halifax Town Council has not yet lost faith in the Goux system of sewage-disposal, which is said to have hitherto worked well.

THE Leigh (Lancashire) Rural Sanitary Authority have found it necessary, from the alarming prevalence of scarlet fever in their district, to issue printed papers containing instructions as to the use of precautious against the spread of the disease. It appears to be particularly rife among the residents of Lowton Common, and to have assumed there a more than usually fatal character.

MR. JOHN LIDDLE, medical officer of health for Whitechapel, in a quarterly report on the state of his district, again invites attention to the subject of slaughter-houses. It is generally felt that something should be speedily done to remove the nuisances inseparable from the present loose system of slaughtering cattle. The existence of so many slaughter-houses as there are now in London, with the utterly inadequate supervision of the same, affords facilities for killing diseased animals and for the disposal of unsound meat. These evils would only be overcome by the erection of public abattoirs.

DR. BURDON-SANDERSON announces that the first of his annual course of lectures will this year be delivered at the University of London on Dec. 15th, at 5 o'clock P.M. The subject will be "The Pathology of Inflammation." The lectures will be given on alternate days at the same hour.

THE sanitary authority of the port of Sunderland are following the example of the City Corporation in organising a health department afloat. They have just appointed a sanitary inspector to visit and inspect vessels arriving in the Wear.

THE rate of mortality among officers of the British army throughout India was 12·55 per 1000 in 1873.

Correspondence.

"Audi alteram partem."

SANITARY WORK IN INDIA.

To the Editor of THE LANCET.

SIR,—With reference to your article on the "Prince of Wales and Cholera" and Dr. Sutherland's reply of the 27th ult. and 4th inst., the matter seems to me to resolve itself into the question, as to whether the action taken by the Royal Sanitary Commission has really led to the diminished death-rate of our European troops now serving in India. Dr. Sutherland remarks, that "at the time when the Royal Commission on the Sanitary State of the Army in India began its inquiry in 1859-60, the average death-rate among British troops in India was 69 per 1000 per annum. Last year it was a shade above 13½ per 1000"; and he argues that this change "is the most striking illustration of the effects of these improvements" (sanitary) on the condition of the Indian army. It seems to me, however, that before we can accept this conclusion we must take the following circumstances into consideration. Prior to the year 1859-60, the British forces in Bengal—and I would restrict my observations to this presidency—were almost constantly engaged in active service; and the Army Sanitary Commissioners are well aware of the fact that the casualties of a campaign in India arise in a much greater degree from the seeds of disease sown during the hardships of active service than from the bullets of the enemy. Since 1859-60 our army has led a life of ease and comfort in their barracks; and, in consequence of the extension of our system of railroads throughout India, the troops have been saved from the fatigue of long marches, formerly made during the cold season of the year, in the ordinary course of the annual relief.

From causes which it is unnecessary for me to describe, the Queen's regiments in India, prior to 1859-60, were frequently detained in the country for some years beyond the time allotted to them by the regulations of the service; and three European regiments and the whole of the Artillery were enlisted for local service, and these troops never left Bengal.

Then, again, there having since 1859-60 been no urgent necessity for filling up the ranks, the greater number of men enlisted for the service have been carefully selected before entering the army, so that a remarkably healthy set of young fellows have been sent out to India; and their period of service in the country has been curtailed of late years.

It is necessary also to take into consideration the conditions under which our troops are now invalided, as compared with the practice formerly followed in this matter. For instance, in 1861 the death-rate of British troops in India was some 37·74 per 1000, and the invaliding 31·68 per 1000; but in 1868 the figures were respectively 21·71 and 67·7 per 1000. Changes of this kind in the practice of invaliding sick men from India must evidently exercise a considerable influence on the death-rate of the men remaining in the country. Soldiers who would otherwise have died there are sent home.

Lastly, in estimating the difference between the present and former mortality among our troops, we must take into consideration the fact that the medical treatment of the sick has improved of late years; for the medical school at Netley raised the standard of education among young army surgeons; and it is only during the past fifteen years that large doses of ipecacuanha have been administered with such marked advantage in cases of dysentery, and quinine given in curative doses for the relief of malarial fevers.

Before we can, therefore, determine the amount of credit due to the Army Sanitary Commission for the diminished mortality among our troops, we must decide how far these favourable results are attributable to the fact of our soldiers not having been engaged in active service for some years past, to the alterations that have taken place in the system of invaliding our troops, to the greater care employed in selecting them for the service, and the improved methods of treating them when on the sick list.

The Army Sanitary Commissioners have doubtless exerted themselves in preventive measures against our troops being exposed to the contagion of syphilis, and they must receive all the credit due to them for their successful efforts in this direction.

It seems to me that we may form some notion of the influence exercised by the above-mentioned causes on the health of our soldiers in India by examining into the health conditions of their wives and children. These latter have never been affected by the perils of war; they are not usually invalided when sick, nor are they selected lives to start with on joining their regiments, but they are sanitarily cared for in precisely the same way as their husbands; and, on turning to the last report of the Sanitary Commissioner with the Government of India at my disposal (1872), I find that in the Bengal army the death-rate among the European women in India amounted to 46·12 per 1000, and that of their children to 112·95 per 1000.

I will not enter on a discussion as to the communicability of cholera through means of drinking-water; but I cannot help thinking it would have been well if the Royal Sanitary Commission, acting on the authorities in Bengal, had followed the lead of Mr. Simon and Dr. Parkes regarding the supply of drinking-water consumed by our troops. That such has hardly been the case, at any rate so late as the year 1871, we learn from the following order issued by Lord Napier. He remarked that, "so long as the existing procedure of conveyance in mussucks from different sources, and the storage in numerous receptacles, at all times more or less open to pollution of dust or dirty vessels, exists, so long is it fruitless to expect anything but comparatively foiled results." This remark by the Commander-in-Chief was made ten years after the Royal Sanitary Commissioners had commenced their work in India.

I can only add, that I do not know of a single cantonment in Bengal (excluding the Presidency) in which an efficient system of drainage or water-supply has been introduced. The sanitary state of the civil population has not improved, and in certain districts it has degenerated during the last fifteen or twenty years; and it is remarkable that although a deadly fever raged from 1861 to 1871 throughout a province of Bengal as large as Ireland, and within sixty miles of Calcutta, even the type of this fever had not been accurately defined, or its conditions systematically examined, up to within the last eighteen months. The gaols of Bengal were vastly improved under the auspices of Dr. F. Mouat, but his plans were completed before 1859–60, and the health of the prisoners has not improved since he left India. Cholera is as deadly at present among the civil population (and, I believe, among the military also) as it has ever been, and no persistent efforts have as yet been made to mitigate the frightful ravages of this disease among the natives of Bengal.

Yours faithfully,
Grosvenor-street, December 6th, 1875. C. Macnamara.

MILITARY MIDWIVES.

To the Editor of The Lancet.

Sir,—In your impression of the 27th inst. I observe a letter from Staff Surgeon Nelson, R.M.A., upon the propriety of providing well-educated midwives for the army, in order to secure the comfort and well-being of our soldiers' wives and infants during labour, and to render them independent of the ignorant "Gamps" who are always to be found infesting garrison towns.

So far back as 1869 I formed a school for army midwives, in connexion with the training department for civilian midwives, at Sir P. Dun's Hospital, Dublin, to which is attached a large and flourishing midwifery department, I was encouraged and aided in this work by H.R.H. the Field Marshal Commanding in Chief; the then head of the Army Medical Department; my esteemed friend Doctor Dane, the then P.M.O. of Ireland; and also by my Board of Governors.

The school has been for the last five years in a most prosperous condition, and has recently been placed upon a firm basis by the patronage of Her Most Gracious Majesty the Queen. It is in active operation throughout the year. Since its foundation in 1869 up to the present date, I have educated 271 well-informed midwives and ladies' nurse-tenders, and these are now scattered over the empire with their respective corps.

An Army Midwives' Class is now under training.

I have the honour to be, Sir,
Your obedient servant,
Edward B. Sinclair, A.M., M.D.,
King's Professor of Midwifery, Univ. Dub. Medical School,
once Assistant Surgeon to the Royal Scots.
Dublin, Nov. 1875.

ON DILATATION OF THE FEMALE URETHRA.

To the Editor of The Lancet.

Sir,—Mr. Teale's recent paper on the Treatment of Vesical Irritability in the Female by Dilatation of the Urethra, shows that he and I have unconsciously been working in parallel grooves for some time. I was not aware of Mr. Teale's practice when, in 1871, I adopted a very similar proceeding at the Hospital for Women, Soho-square, to which institution I was then surgeon. Failing to cure cases of painful micturition by other measures, I adopted the plan of rapid dilatation of the urethra with the finger guided by a director, in some cases using a pair of ordinary polypus forceps to commence the dilatation. My idea was that, in some cases, there was a fissure of the mucous membrane analogous to fissure of the anus, but this I was never able to prove, though the rapid dilatation almost invariably produced a tear in the subpubic portion of the mucous membrane, which might, in some cases, be the continuation of a fissure. In a course of lectures on Diseases of the Female Urinary Organs, which I delivered at Soho-square in February, 1873, I narrated many cases illustrating this practice, and from the number of American surgeons who at that time visited the hospital and saw my practice, I imagine that the introduction of the practice into America is due to my example. I can fully confirm Mr. Teale as to the benefit conferred on many cases by the treatment and its failure in others, and I have never seen permanent incontinence result, though my patients have often been unable to retain the urine for twenty-four hours. I have, however, never pushed the dilatation quite to the extent practised by Mr. Teale, having been content to take one finger as my limit.

In another direction, however, I have pushed on somewhat beyond Mr. Teale, and that is in the application of topical treatment to the female bladder. In cases of chronic cystitis, with purulent urine, I have detected, as I believe, an ulcerated condition of the mucous membrane (for with the left forefinger introduced into the bladder it is easy with the other hand to bring the whole of the mucous membrane into contact with it), and I have then applied a strong solution of nitrate of silver by means of a mop, securely fastened on a wire, and passed through a small vulcanite speculum introduced into the urethra. The effect of this has been, in many cases, to render the urine acid and clear in twenty-four hours, and the tolerance of the remedy by the bladder is remarkable. The solution I have employed has been as strong as three drachms to the ounce, and I have never seen any harm follow even where little permanent good was done.

Yours obediently,
Christopher Heath, F.R.C.S.
Cavendish-square, December, 1875.

THORACIC ANEURISM IN ITS RELATION TO SYPHILIS IN THE ARMY.

To the Editor of The Lancet.

Sir,—I regret having been absent when the interesting subject of Thoracic Aneurism in its relation to Syphilis in the Army was discussed at the Medico-Chirurgical Society. Permit me now to say a few words on a subject in which I feel much interest.

Notwithstanding a somewhat lengthened period of military service, I confess that I should hesitate to attribute the occurrence of aneurism of the aorta to one particular morbific influence. Granting that degeneration of arterial tissue, consequent on syphilis, may tend to induce aneurism, I would, nevertheless, consider that long-continued habits of intemperance—not necessarily periodical, or great excess in drink—is a more frequent origin of the disease.

Space does not here permit me to enter into the question which of these two exciting causes exercises the most pernicious influence on the circulatory system in civil, as well as military life. I feel, however, disposed to think that in cases of disease of the heart and its vessels, both among soldiers and civilians, syphilis does not bear so important a part as alcohol. Very frequently, indeed, the connexion between drink and such diseases has come under my observation, and the same remark applies, in a lesser degree, to acute rheumatism; but, speaking from memory, I cannot recal one autopsy for aneurism in which a marked impairment of constitution, traceable to syphilis, was evidenced. Then, how are we to distinguish between the morbid influences of syphilis and intemperance when, as so very often is the case in the army, they go hand in hand? Difficult, if not impossible.

A third and important exciting cause of this class of disease —pressure from military clothing and appointments—is a well known and acknowledged fact, which needs no comment.

It must borne in mind, that patients affected by aneurism not unfrequently attribute the origin of their complaints to some sudden strain. This circumstance points rather to pre-existing arterial degeneration from one or other of the two first-named causes. The last one—the soldier's dress—I should say, shows its evil consequences more in the generation of hypertrophy and valve disease.

It has, for some time past, been my impression that both aneurism and heart disease are much more frequently met with in the army of late years—that such diseases are on the increase.

Looking back for a period of nearly thirty years, death from aneurism was, in my own experience, infrequent. During an interval of five years which I passed in a line regiment not one occurred, and a considerable interval elapsed after I joined the Guards before the contigency arose. And yet formerly, when long service was the rule a soldier remained much longer under the observation of the medical officer.

If my theory be correct, to what cause may the circumstance be attributed? Was the old coatee and its deplorable adjunct of a military stock less injurious than the tunic? Certainly not. Or were the habits of the men better?

I would rather rest my inference on the ground that ever since the Crimean war the physique and morale of the recruit have deteriorated; that, consequently—and to a marked extent of late years—the men are incapable of resisting in the same measure the various prejudicial influences to which they are subjected either by military duty or by evil propensities.

I am, Sir, your obedient servant,
Fred. Robinson, M.D.,
Scots Fusilier Guards.
Claverton-terrace, St. George's-road, S.W.

THE UTERUS OF HARRIET LANE.

To the Editor of The Lancet.

Sir,—Will you kindly allow me to correct one mistake in your report of the "Note on the Post-mortem Diagnosis of a Nulliparous Uterus" which I read at the last meeting of the Obstetrical Society. The measurement of this uterus at the fundus was not one inch and three-quarters in width, but one inch and a third.

Again: It was not from the special character of this particular uterus that I thought it impossible to form a positive opinion with regard to the existence of a previous pregnancy, but because I hold that to be a general rule. My contention at the late trial was that there was no *proof* of a previous pregnancy; but that, on the contrary, so far as appearances went, the uterus indicated rather the opposite. I am generally credited by the newspapers with having given a positive opinion that this uterus had not borne a child; whereas, the only positive opinion I gave was that no one could tell whether it had or not; but I inclined to the opinion that this had not, and I gave reasons which, in the present state of our knowledge on the subject, I believe are fairly warranted, especially in a doubtful case where issues of life and death are involved.

I am, Sir, your obedient servant,
George-st., Hanover-sq., Dec. 1875. Alfred Meadows.

SANITARY CONDITION OF UPPINGHAM.

To the Editor of The Lancet.

Sir,—I am desired by the Sanitary Authority of the Uppingham district to forward you the subjoined report of their medical officer and engineer for publication.

Yours faithfully,
William H. Brown,
Uppingham, 8th December, 1875. Clerk to the said Authority.

Report

"*To the Chairman and Members of the Rural Sanitary Authority of Uppingham.*

"Gentlemen,—Hearing that the masters of the Uppingham School will probably meet on Friday next, when we presume they will take into consideration the re-opening of the school, we deem it our duty, as the reports we are preparing are not finished, to present an interim statement.

"We find that the condition of several of the school-houses is such as to necessitate material alterations in their sanitary arrangements. With a view to facilitate such alterations Mr. Rogers Field, your engineer, has, in accordance with your resolution, placed himself in communication with Mr. Tarbotton, engineer to the schoolmasters, and he has every reason to believe that means are being taken by the school authorities to expedite the necessary works. Until, however, these are completely carried out, so as to enable us to report to you that each individual house in connexion with the school is in a perfect sanitary condition, we think it desirable that you should not in any way countenance a premature return of the scholars.

"We are, gentlemen, your obedient servants,
"Alfred Haviland,
"Medical Officer of Health to the Rural Sanitary
"Authority of Uppingham;
"Rogers Field,
"Civil Engineer.
"4th December, 1875."

THE WHITECHAPEL MURDER.

To the Editor of The Lancet.

Sir,—I see by your leading article in reference to the above case that you say "the witnesses relied entirely upon the evidence afforded by the wisdom teeth" to determine the age. In justice to myself I think it right to say that I specially examined the ossification of the several parts of the sternum, as well as the *dentes sapientiæ*, in order to assist me in arriving at the probable age, which I gave as *about* twenty-five years.

Again you say—"It is certainly surprising that neither side made any attempt to demonstrate the presence or absence of *lineæ albicantes* upon the abdomen." This, too, is a mistake; and I am quite sure you will be amused by the observation from the Lord Chief Justice in reference to my evidence on this point, that he did "not see what that had to do with it!" It is not my fault that other very important evidence was not given, which would go very far to establish, beyond any reasonable doubt, the fact of pregnancy. I tried to confine my observations closely to the exact questions put to me. Suffice it to say, that I had taken care to give my reasons fully in my reports to the prosecution, and in reply to my observation thereon, Sir John Holker said, "there was ample evidence," or something to that effect—as proved by the result of the trial. I have been requested by several persons to report my evidence as to pregnancy *in extenso*, which I will do. I believe my colleague in this case, Mr. Bond, has promised to send you a report.

Yours truly,
F. G. Larkin.
Trinity-square, Southwark, S.E., December, 4th, 1875.

BIRMINGHAM.

(*From our own Correspondent.*)

The scheme propounded for the sanitary improvement of the town by the adoption of the Labourers and Artisans' Dwellings Act, to which attention was called in a previous article, is about to be increased in magnitude and importance. At their last meeting, the Town Council decided, on the recommendation of Dr. Hill, the medical officer of health, to deal with a large district contiguous to that already scheduled, and comprising not less than fifty acres of land. Narrow streets, close courts, houses built back to back, insufficient space, dilapidation, and bad drainage, combine to make this part of the town very unhealthy. While the average death-rate of the borough last year was 26·78, the death-rate in some of the streets in the proscribed area was 54, and in one street reached the frightfully high ratio of 73 per 1000. The proposal to extend the scheme originally suggested will involve a great outlay, but I believe that in the long run it will prove, as at Glasgow, to be a financial success, while the benefits it will confer on the town as a sanitary reform are simply incalculable. Dirt, drunkenness, disease, and death are costly companions, and they will not be banished from the town until the working classes have healthy homes, better education, and more rational sources of enjoyment and pleasure than the public-house and the liquor vault now afford them. Schools established under the Education Act are already raising the intellectual standard of the rising generation, but these will fail in their aim if the children are brought up in dirty houses and in squalid streets and alleys, and have not their physical condition also considered in the establishment of more numerous and extensive play and recreation grounds, at which the sports and pastimes that encourage the growth of healthy muscle and bone can be indulged in.

The Committee of the Midland Medical Institute have arranged with the authorities of Queen's College to occupy some of their rooms at a rental of £200 a year. It is far better that the medical reference library should be located here than at any place at a distance from the medical school. Students as well as teachers will alike benefit by the proposed arrangement.

The periodical collections for the Queen's Hospital in the various churches and chapels of Birmingham have this year realised over £5700, a larger sum than has ever before been collected on Hospital Sunday, and a sufficient answer to those who urged that the adoption of the "free system" would diminish the number of friends and supporters of the charity.

The late Mr. George Allarton, whose obituary you gave last week, was much respected in this town by many of the older members of the profession who knew him during the time he practised at West Bromwich, and who adopted and still perform his modification of the median operation of lithotomy.

Francis Warner, M.D. Lond., having been recently elected assistant-physician to the Children's Hospital, after a contest with another graduate of the University of London, a gentleman congratulated the governors of the hospital on the fact of their having two such excellent candidates, and remarked that theirs was the only hospital in the kingdom whose medical staff were graduates of London, a distinction which he hoped would be maintained.

You have already called attention to the success which attended Dr. Richardson's inaugural address at the Midland Medical Society, and to the presentation of a testimonial to the worthy treasurer, Mr. James Harmar. In future that Society will exist only for "the promotion of scientific and practical medicine and surgery by the delivery of addresses, the reading and discussion of papers, and by pathological and other demonstrations." The books and periodicals are handed over to the Midland Medical Library, and the reading-room will be transferred to Queen's College.

Nov. 15th, 1875.

GLASGOW.

(*From our own Correspondent.*)

THE first annual meeting of the Western Infirmary of Glasgow was held on the 25th ult., and the report presented by the secretary was, on the whole, satisfactory. The ordinary income had fallen short of the ordinary expenditure by £1399, but the deficit was covered by the result of a special appeal to the public in May last, when a reserve fund was obtained of £3736. With regard to the financial future some of the speakers took a rather doleful tone, and indicated that unless there was increased liberality it might be expedient to curtail rather than augment the accommodation. Others, and with justice, looked forward hopefully, and trusted that as the needs and benefits of the institution became more widely known, there would be no necessity for any special subscription fund. In the interest of medical education we trust the hospital will be still further extended. There are now, we understand, upwards of 200 medical students attached to the University, and when the session commenced there were only 141 patients in the hospital. It is obvious that this is far too small a number for the purposes of clinical teaching.

The annual dinner of the Faculty of Physicians and Surgeons was held on the 26th ult. in the Faculty Hall, under the genial presidency of Dr. Fergus. "Floreat res medica," the toast of the evening, which a well-known judicial authority has translated, "Let disease continue and doctors flourish," was given from the chair, and responded to with hearty enthusiasm. In replying to the toast of the "House of Commons," Dr. Cameron, the Liberal, and Mr. Whitelaw, the Conservative member for Glasgow, both referred to the importance of having more medical men sitting in the legislative assemblies, and Dr. Cameron observed that while other professions were honoured by a seat in the House of Peers, it was an anomalous fact that there was no medical representative there. A justly esteemed medical man shook his head and negatived the idea. Dr. Cameron, observing this, humorously stated that perhaps the objector would be contented with a Baronetcy, but that he still maintained that a medical peer was a necessity, and might yet become a Radical grievance. Perhaps the most important statement of the evening was made by Dr. Geo. Buchanan, who, in replying for the University of Glasgow, declared that, consistent with the ordinances, every extra-mural lecturer would be recognised by the University Court. This announcement, which was doubtless made on authority, was hailed with satisfaction. There can be little fear of a hospital languishing for public support, connected as it now is with a university which has cast off ancient traditions and, in inaugurating such a liberal programme, has become in unison with the spirit of the age. The faculty is in a very flourishing condition; the number of junior fellows who have entered during the last two years evinces a considerable increase as compared with the past. The scale of fees as sanctioned by the faculty ought to be altered. Glasgow boasts of being the second city of the empire, but its merchants have no hesitation in paying medical men at half-a-crown a visit. Such a sum might have been sufficient when the Clyde could be crossed on stepping-stones where the Atlantic liners now anchor, but it is absurdly small for the wealth and present position of Glasgow. It is certain that a strong and united effort on the part of the faculty would place things on a better footing, and make this town a field for professional success second to none in Great Britain.

A few days ago an article appeared in one of our daily papers, inspired either by a candid friend or secret foe, and revealing a sad state of matters in the class of Physiology in the University. It appears evident, from the correspondence which has ensued on the subject, that years are telling on, and voice is failing, the present occupant of the chair, Dr. Andrew Buchanan, for it is stated that only the students on the first or second bench can detect the subject of the veteran lecturer's discourse. While this fact has been broadly mooted, and not contradicted, yet all the students, both past and present, who have taken part in the correspondence, speak with the greatest respect of one who has undoubtedly done much good work in his day. It is evident that a crisis has occurred, and that a change is imminent in the teaching of physiology; and, looking at the matter impartially, it is to be hoped that Dr. Buchanan will imitate his friend and former colleague, Dr. Rainy, and retire from a field in which he has worthily won his spurs. The discussion shows very clearly and pertinently the necessity for the recognition of extra-mural lecturers and for free trade in teaching.

Glasgow, Dec. 6th, 1875.

P.S.—Professor Andrew Buchanan has intimated to the University Court his resignation of the Chair held by him.

IRELAND.

(*From our own Correspondent.*)

THE first meeting of the Medical Society of the College of Physicians, Ireland, took place on Wednesday, Nov. 10th. The President, Dr. Samuel Gordon, in his inaugural address, mentioned with approval the epidemiological reports which of late have formed a part of the proceedings of each session. He instanced the success of the efforts which have been often adopted of late, in arresting the spread of so serious and infectious a malady as scarlatina, and paid a just tribute to the value of preventive medicine in this as well as in so many other diseases. The death of three members of the medical profession at Dublin lately, formed the theme of much of the President's address. Mr. Lestrange was better known in the surgical world by his invention of some important surgical instruments. Professor Law's valuable communications and his carefully recorded cases were of great importance, and led to subsequent valuable discoveries, more especially in reference to cirrhosis of the liver and gangrene of the lungs. Mr. John Hamilton, although not a member of the Society, took an interest in every society for the promotion of medical progress. His illness originated in an attack of dysentery some five years ago; although he appeared quite to have recovered from this attack, a subsequent relapse entailed much suffering, and from this time he was never quite free from obstinate constipation for any length of time; more recently he had an attack of choleraic diarrhœa. Evidence of mischief was afforded by the occurrence of a fissure, tumours, and abscesses, and lastly a communication was formed between the rectum and bladder. The terrible suffering that now arose rendered an operation desirable. Colotomy rendered life more endurable during the few remaining days of Mr. Hamilton's life; and he died, to use the words of Dr. Gordon, a model of faith, resignation, and patience.

Sir Dominic Corrigan, Bart., read his observations on Aix-les-Bains. He commended their efficacy, and while he pointed out some minor matters which he thought might be improved, he spoke generally in very high terms of the arrangements for the benefit of invalids. Dr. A. W. Foot also read an interesting paper on a remarkable case of obesity treated with liquor potassæ and extract of fucus vesiculosus.

The Obstetrical Society held its first meeting for the session on 20th November. The President, Dr. Atthill, spoke at length on some of the theories that have been brought under notice in connexion with the monthly uterine flow.

The very important question, "What is Dublin to do with the Liffey?" is now under the earnest consideration of many who wish well to Ireland's chief town.

An injunction has been obtained by the Citizens' Committee against the expenditure of any more money by the Dublin Corporation on the protracted action by that body in reference to the main drainage question.

Sir John Glover continues to improve daily. He is now able to be up, and we have every reason to trust that his recovery may now steadily progress. He is still under the able care of Mr. Butcher.

A skating rink on the most improved plan is approaching completion near the Exhibition Palace Grounds, Earlsfort-terrace, Dublin.

The extraordinary damp and cold of the present season is tending to spread different forms of zymotic disease now prevalent in Dublin. Of these we may mention—fever (typhus and typhoid), measles, scarlatina, and erysipelas.

Pulmonary affections, and cases of severe attacks of diarrhœa with a tendency to dysentery, demand real activity on the part of the sanitary authorities and the people themselves, especially as the condition of the lodgings of the working and poor classes at Dublin are in so bad a condition in many parts of the old city.

The custom of "waking," even those dead of contagious diseases, continues unchecked by the authorities.

The Dublin barracks have lately had a somewhat unhealthy reputation; it is but justice that this matter should be more fully inquired into. Dublin itself has need of improvement in the same direction, and steps have already been commenced with that intention. Indeed, from a combination of causes, notably, as it would appear, from the severe and wet character of the last few months, many of the old houses in the more ancient parts of Dublin have given evidence of great danger to their inmates from indications of actual falling; and to tell the truth, at least five or six houses quite lately have thus come to grief, happily with but little loss of life. Enough of mischief has, however, happened in this way to stir the civic authorities to active measures, so far as their powers extend. Several streets and lanes in the older parts of Dublin now present numerous hoardings and many buildings in progress of demolition. Such measures, provided sufficient new buildings be provided for those who may be deprived of homes by the removal of the old houses, cannot but exert a highly beneficial influence on the health of the Irish metropolis, including the troops quartered therein.

The necessity for improved huts on the Curragh is finding expression in the daily journals at Dublin. The *Irish Times* forcibly draws attention to the matter, pointing out that the good of the public service loudly demands attention to that question.

A monument to Grattan has just been erected at College Green; it awaits unveiling.

I have just availed myself of an opportunity of visiting the Richmond barracks, which stand on a somewhat elevated plateau, some three miles south-west of the General Post Office. On the south the barrack grounds are bounded by the grand canal, on the west by a valley of some depth through which flows a stream providing natural drainage on that side, and at some distance also on the north of the barracks, as it flows eastwards on that side. The ground slopes by a gradual descent from the site of the barracks towards the east. The buildings are apparently about fifty years old, and surrounded by a large parade ground, enclosed by strong walls. The accommodation is considered good, and provides for a force of about 1000 men. During the present season, as well as in the last summer and autumn, but two cases of enteric fever have occurred in this barrack, and in both cases recovery took place. An outcry has been raised against the water supply, which is derived from the canal, and some have called for a supply of the Vartry water, with which Dublin is supplied. There is no doubt that a certain amount of organic impurity is to be found in the canal water, especially in the summer and autumn months. On the other hand, however, there are those who argue that the lime salts which are present in the canal water under consideration are eminently useful and even necessary for the proper nourishment and growth of the human race, as well as for other animals. In this respect the Vartry water is almost absolutely pure. There are many sanitarians who incline to the belief that a certain amount of hardness is beneficial in water as an article of diet, although it may be admitted that it is a quality which is objectionable in other ways, as in cooking, washing, &c. Whether the source of water supply be taken from the canal as at present, or from the Vartry, it is advisable, in the interests of civilians and the military alike, that very strict attention be paid to the prevention of access of organic matter to each source of supply.

At the meeting of the Dublin Pathological Society (Dec. 4th), the President of the College of Surgeons exhibited a case of chronic rheumatic arthritis. Mr. Hamilton also exhibited a case of extra-capsular fracture of the femur, with impaction and transverse fracture immediately below. Dr. Grimshaw brought forward a case of colloid cancer of the great omentum. Mr. Wilson exhibited an eyeball removed from a man 77 years of age. It was a dark black mass, without any organisation whatever. On microscopic examination, it was seen to be an instance of ordinary pigmented spindle-celled sarcoma. Dr. Atthill exhibited an example of imperfect development of the rectum in a fœtus. Dr. Robert McDonnell made a communication on securing bloodvessels by torsion.

The extreme severity of the weather has produced a considerable increase of sickness in Dublin as elsewhere. Pulmonary affections—a form of catarrhal febrile attack, accompanied with a good deal of prostration—has become common; whilst the existence of some cases of severe typhus, some of typhoid fever, as well as of cases of scarlatina and measles, warns us to be up and doing in sanitary improvements.

The Sanitary Association here is again drawing public attention to the noxious influence exerted by the depôts of fetid organic matter which exist so numerously in Dublin. The Dublin Main Drainage Question still hangs fire, and it is to be hoped that the most approved system will be carried out, and that all persons concerned will use their best endeavours to bring about a system which, while it must be suited to the already heavily-taxed resources of the citizens, may fulfil the requirements of the population.

PARIS.

(*From our own Correspondent.*)

OPENING OF THE SCHOOL OF MEDICINE AND THE PARIS CLINIQUES.

IN my last letter I spoke of the forthcoming opening of the winter session of the Faculty, and gave you a programme of the lectures which the professors and the various hospital physicians and surgeons were preparing to give. On the 3rd inst. the School of Medicine threw open its doors, and the same day Professor Gavarret lectured on Heat, M. Duguet on the Diseases of the Urino-genital Organs (opening lecture), Professor Sappey on Anatomy, and Professor Chauffard on the Comparative Character of Acute and Chronic Disease.

The clinical teachers in the hospital have likewise been busy at work the whole of last week. The three professors at La Charité inaugurated their teaching, and in doing so they all seemed impressed with the necessity of giving an additional impetus to the clinical teaching of the Faculty in view of the rival schools, and especially the Catholic ones, which are about to be established on the strength of the new laws on freedom of teaching. All three of them expressed themselves very energetically on the subject. Professor Sée declared that the necessity of studying seriously was greater now than ever. The rival Faculties were still in a state of embryo, but it was necessary to begin work at once. The standard of clinical teaching should be raised higher than ever. "On this ground," exclaimed the Professor, "we can bid defiance to our adversaries; and, as to myself, I feel the younger for the conditions which the laws on freedom of teaching have imposed."

M. Trélat expressed the same views on the question, and especially insisted on the following train of thought: "In view of the rival schools which are about to be established, the time is come when all of us, masters and pupils, must rally around a common flag—that which we owe respect to, and faith in, scientific truth. What man has gained by science it is our duty to maintain, and this appropriation of knowledge constitutes a patrimony which we must respect and defend. To have faith in the progress of science, to adhere to the truths which it teaches, is our honour and our dignity. By tightening, through our labour, the bond which unites us we shall follow the way traced out by illustrious predecessors, and we shall not be unequal to the task we have before us."

The foundation of new faculties, and especially the rival teaching of the Catholic party, are much talked about by the medical body, and form the subject of every conversation. There is no doubt that much anxiety is entertained as to the results of these most radical changes. At the same time, there is no doubt that the spirit of competition is working good effects, and has produced throughout the whole body of teachers in the school or the hospital an earnestness and a zeal for labour and success which must be highly useful.

Before leaving the *cliniques* of La Charité, I may just add that, in addition to their general remarks, M. Trélat gave a very substantial lecture on the Diagnosis of Tumours of the Breast, whilst Prof. Sée judiciously insisted on the necessity of giving more importance to the therapeutics of clinical teaching, and stated his intention to devote two of his lectures, out of three a week, to the therapeutics of cases, and only the third to comparative diagnosis. His first lecture was on the Action of Drugs in General. As to Prof. Gosselin, the third lecturer at La Charité, he resumed his admirable lectures by a comparative description of several cases under treatment.

At the Hôpital des Enfants, Dr. Simon opened his lectures by a study of Infantile Paralysis, and at Cochin Dr. Bucquoy commenced with a lecture on Uræmia, in connexion with a case under observation.

No decision has yet been taken as to the nomination of the Dean, the two Assessors, and the two new Professors of the School, in place of Professor Bouillaud, who has retired, and the regretted Lorain, whose death I mentioned in my last letter. Maurice Raynaud, the learned author of "Molière and his Times," will very likely be nominated to the chair of History of Medicine, whilst Potain, the celebrated "clinician" of Necker Hospital, is almost certain to get the chair of Pathology.

The pulling down of the building which the "Assistance Publique" made use of as a central bureau for all the Paris hospitals will very probably give rise to an important change connected with the distribution of patients amongst the hospitals. Every hospital here can daily admit a certain number of patients presenting themselves directly to the house-surgeon on duty, but, on the other hand, a fixed number of beds is reserved for the Central Bureau, where patients present themselves, and whence they are distributed over the various hospitals, which, as you know, are all under one and the same administration. This entailed a great loss of time and great difficulties on patients, who were obliged to go from all the various and most distant quarters of Paris to the Central Bureau near Notre Dame, there to get tickets of admittance and afterwards to proceed to their respective hospitals, some of which are situate at great distances. In order to reform this, the Prefect of the Seine has suggested a plan by which there would be a small bureau of admittance in every *arrondissement* of Paris, connected with a central office by means of the telegraph. Each bureau would serve for its special quarter of the city. There is no doubt that this would be a great improvement on the present order of things. The authorities at the Assistance Publique hesitate, however, on account of the great increase in the number of medical officers which the reform would involve.

Amongst the recent measures brought for approval before the National Assembly, is one for the pulling down of the Ecole Pratique and the Hôpital des Cliniques, situate opposite the School of Medicine. The Ecole Pratique has become much too small and encumbered for the present requirements of the School of Medicine, and constitutes, besides, a cause of much complaint in that quarter of the town, as it contains the dissecting-rooms of the Faculty.

DEATH OF GIRALDÈS.

It is with great grief that I have to mention the death of the most learned of contemporary French surgeons, my respected master and friend, Dr. Giraldès. On Saturday morning I received a note which had been written on the evening before by Dr. Hahn, the librarian of the School of Medicine, and in which, knowing the friendship that existed between Dr. Giraldès and myself, he had hastened to inform me of the melancholy circumstances which had attended the death of Dr. Giraldès. At about seven the same evening, Dr. Giraldès had called at the library of the Faculty, when suddenly he felt ill, and began spitting blood. Dr. Hahn put him in a cab, and was accompanying him home, when about half way from the school to his house, Dr. Giraldès died in the arms of Dr. Hahn without any apparent suffering.

I enter into all these particulars because I know how many friends Dr. Giraldès reckoned in England. He was personally known, and most highly liked and esteemed, by Sir James Paget, Prescott Hewett, Holmes, Jonathan Hutchinson, Birkett, Critchett, Bowman, and many others, who, I know, will regret his loss very severely.

Dr. Giraldès was most remarkable for his erudition, which was one of the ornaments of modern French surgery. He was deeply versed in the surgical literature of every country, but most especially that of England. The most minute details of the history or modes of operations, the slightest anecdotal particulars relating to the advance of surgery in Great Britain, or to those who promoted its progress, were familiar to him. In all the academies or societies of which he was a member he rendered invaluable services by his complete and extensive knowledge of foreign surgery, and he invariably formed part of every committee appointed to investigate questions having a foreign connexion.

His erudition was not a matter of mere memory; it was a complete and careful storing up of facts, synthetised, compared together, sifted, and examined by a mind of remarkable keenness, and with solid judgment. These latter qualities were most conspicuous in his intellectual disposition. He had a quiet, sarcastic manner of disposing of so-called discoveries, a power of common sense and judgment which, added to his wonderful knowledge of facts, made him one of the most valued members of professional bodies.

He was a hard worker in the field of surgical science—actively engaged from early morn to evening, either in his wards in the hospitals or in his study, or in his practice in town, in the search for something to elucidate a problem or simplify a proceeding, something to do justice to whom it was due, or to alleviate the sufferings of humanity.

He had identified his name with the surgical wards of the Hôpital des Enfants Malades, where for several years he practised the surgery of children, and delivered most interesting and remarkable lectures on the subject. His lectures have been gathered and edited by one of his talented house-surgeons, Dr. Bourneville, and they form a most valuable book—a lasting production of the eminent man from whom it came, and a volume to be possessed by all who care to know the surgery of children.

I cannot in these hurried lines allude to all Dr. Giraldès' other titles to scientific eminence, to the esteem of his contemporaries, and the recollection of posterity.

As to his eminent qualities of mind and character, his independent and liberal spirit, his love of justice, his unbounded devotedness to his friends and pupils, I, who lived in his intimacy and was attached to his wards, can testify with the strongest feelings of personal gratitude and admiration, and I am confident that all who enjoyed his friendship will share this feeling.

Paris, Nov. 30th, 1875.

Medical News.

APOTHECARIES' HALL. — The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on Dec. 2nd :—

Broome, Stephen Bernard, Camden-street.
Elcum, Donald, Warwick House, Cheltenham.
Houchin, Edmund King, High-street, Stepney.
Whitfield, William Clarke, St. Owen-street, Hereford.

The following gentlemen passed the Primary Professional Examination on the same day :—

Henry Frederick Bailey and John Gairdner, University College ; William Henry Rean, London Hospital.

THE Town Council of Londonderry last week re-elected Dr. William Miller to the office of Mayor.

AT a meeting of the Municipal Council of the City of Dublin, held last week, Dr. George B. Owens, J.P., was unanimously elected Lord Mayor of Dublin for 1876.

A man named Savage died in Kerry last week after completing his one hundred and sixteenth year. He was born in 1759, and three years ago voted at an election at Listowel.

Dublin Pathological Society.—The subject for competition this session is "On Bursitis, and its Pathology," and the author of the best essay sent in by students who attend the meetings of the Society is presented with a gold medal, value £5.

Royal Medical Society, Edinburgh.—The following is the list of office-bearers of this Society for the session 1875–76:—Presidents: Dr. A. R. Turnbull, Dr. A. R. Coldstream, Dr. Thos. R. Ronaldson, and Dr. Thos. D. Wilson. Hon. Secretaries: Mr. George Ogilvie, and Mr. Leslie Ogilvie. Curator of Library: Dr. J. J. Cox. Curator of Museum: Dr. J. Graham Brown. Hon. Treasurer: Mr. J. R. Young. Sub-Librarian: Mr. John Turner.

Water-supply.—At a meeting of the council of the Metropolitan Poor-rate League held last week, the form of a memorial to the Home Secretary on the water-supply question was agreed upon. The memorialists ask that the supply shall be placed in the hands of a governing body elected by the ratepayers; that immediate action be taken to prevent any increase of charge being made upon the anticipated increased assessments; and that the term "annual value" in the Companies Acts be defined to mean the "rateable value" and not the gross "annual value." It was also determined that the subject of local taxation generally should be brought under the notice of the government and the ratepayers.

The London Sick Poor.—At the regular meeting of the Metropolitan Asylums Board in Spring-gardens, on Saturday, Dr. Brewer presiding, it was shown that fever was somewhat diminishing among the pauper class, and that from small-pox the same class is wholly free, not one case being in hospital. At the Homerton asylums for fever there were 199 cases, as against 208 the previous fortnight. Of those remaining 139 were of scarlet fever, 39 of enteric, 11 of typhus, and 107 of other diseases. At Stockwell asylum there were on Saturday 114 cases of scarlet fever, as against 116 a fortnight ago, 27 cases of enteric fever, 1 of typhus, and 2 of other diseases, making in all 144. It was reported to the managers that the Commissioners in Lunacy had inspected the temporary imbecile asylum for children at Clapton and the imbecile asylum at Hampstead for adults, and the reports read expressed satisfaction with the general condition of the patients. Plans were laid before the Board for erecting administrative offices on the sites for asylums at Hatcham, Fulham, and Hampstead, and the cost in each case, it was stated, would not exceed £10,000. It was agreed that the plans should be presented to the Local Government Board.

Medical Appointments.

Allen, R. G., M.R.C.S.E., has been appointed Resident Physician to the Queen's Hospital, Birmingham.

Bigger, S. F., M.R.C.S.E., has been appointed a House-Physician to the Royal Infirmary, Liverpool.

Branfoot, H. S., M.B., M.R.C.S.E., has been appointed House-Physician to the Radcliffe Infirmary, Oxford, vice Rayne, appointed Assistant-Physician to the Manchester General Hospital and Dispensary for Sick Children.

Cunningham, C. L., L.R.C.S.Ed., L.M., has been appointed Medical Officer to Bradshaw's Charity, Ore, Hastings, vice Cumming, resigned.

Dobbie, R. J. A., M.R.C.S.E., has been appointed Resident Medical Officer to the Dover Hospital and Dispensary, vice Pasley, who has received a Colonial appointment in the Island of Trinidad.

Edwards, F. S., M.R.C.S.E., has been appointed a House-Surgeon to St. Bartholomew's Hospital.

Emms, A. W., M.R.C.S.E., has been appointed a Medical Officer to the Leicester Provident Dispensary, to reside in the village of Belgrave.

Evans, D. T., M.R.C.S.E., has been appointed House-Surgeon to the Denbighshire Infirmary, Denbigh, vice Lloyd, resigned.

Farrar, C., M.D., L.F.P. & S. Glas., L.M., has been appointed Medical Officer of Health for the Chatteris Urban Sanitary District, vice Wilson, appointed to the Rochdale Urban Sanitary District.

Fowler, T., L.K.Q.C.P.I., L.M., L.R.C.S.I., has been appointed Medical Officer for the Thoydon-Garnon District of the Epping Union, Essex.

Greenfield, W. S., M.D., M.R.C.P.L., has been appointed a Physician to the Royal Infirmary for Children and Women, Waterloo-bridge-road, vice Sparks, resigned.

Horsley, J., F.C.S., has been appointed Public Analyst for Merthyr: 10s. 6d. per analysis; and 21s. per day, second-class travelling expenses, and hotel charges, when required to give evidence.

Hough, J., M.R.C.S.E., has been appointed Medical Officer to the Borough Gaol, Cambridge, vice Hammond, deceased.

Johnston, W., M.D., C.M., has been appointed a Medical Officer to the Leicester Provident Dispensary, vice Wilby, deceased.

Joynes, F. J., M.R.C.S.E., has been appointed Medical Officer to the West Gloucester Friendly Society, Dursley, vice D'Oyle, deceased.

Kite, J. A., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the whole of the Welwyn Union and the Workhouse, vice King, resigned.

M'Lachlan, S. F., M.B., C.M., has been appointed House-Surgeon to the Chorlton-upon-Medlock, Rusholme, and Moss-side Dispensary, Manchester, vice Daly, resigned.

M'Master, R. D., L.R.C.P.Ed., L.R.C.S.Ed., L.M., has been appointed a House-Physician to the Royal Infirmary, Liverpool.

Malcomson, J. A., M.D., C.M., L.M., has been appointed Medical Officer of Health for the Middlesborough Rural Sanitary District: £150 per annum.

Meehan, N. J., M.D., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Oulart Dispensary District of the Enniscorthy Union, Co. Wexford, vice M'Swiny, resigned.

Owen, W., M.R.C.S.E., has been appointed Medical Officer for No. 6 District of the Parish of St. Matthew, Bethnal-green, vice Sarvis, deceased.

Shain, W. F. [not "J. M.," as stated on p. 823], has been appointed a House-Surgeon to the Royal Infirmary, Liverpool.

Shuter, J., M.A., LL.B., M.B., M.R.C.S.E., has been appointed Assistant Demonstrator of Physiology at St. Bartholomew's Hospital.

Smith, J. B., M.A., M.B., has been appointed Resident Surgeon to the Queen's Hospital, Birmingham.

Smith, W. A., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Clogher Dispensary District of the Clogher Union, Co. Tyrone, vice Scraggs, resigned.

Sterling, R., L.R.C.P.Ed., L.R.C.S.I., L.M., has been appointed Medical Officer and Public Vaccinator for the Eastern District of the Christchurch Union, vice Brash, resigned.

Sutherland, W., L.R.C.P.Ed., L.F.P. & S. Glas., has been appointed Medical Officer for the Rothley District of the Rothbury Union, Northumberland, vice Brodie, resigned.

Thomson, W., M.D., has been appointed Medical Examiner to the Customs for Ireland, vice Hamilton, deceased.

Walsh, T. B., L.R.C.P.Ed., L.R.C.S.Ed., L.M., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Ballyclough Dispensary District of the Mallow Union, Co. Cork, and Medical Attendant to the Royal Irish Constabulary, Ballyclough, vice Harrison, appointed Medical Officer for the Doneraile Dispensary District of the Mallow Union.

Wilson, J. H., M.B., C.M., has been appointed Assistant-Surgeon to the Leith Hospital, vice Vetch, resigned.

Wilson, T. D., M.A., has been appointed House-Surgeon to the Leith Hospital, vice Daniel, resigned.

Births, Marriages, and Deaths.

BIRTHS.

Bullock.—On the 30th ult., at Isleworth, the wife of Henry Bullock, F.R.C.S.E., of a daughter.

Charteris.—On the 5th inst., at Blythswood-square, Glasgow, the wife of Matthew Charteris, M.D., of a son.

Hurd-Wood.—On the 2nd inst., at Great Bardfield, Essex, the wife of J. Hurd-Wood, M.D., of a daughter.

Lydall.—On the 2nd inst., at Mecklenburgh-square, the wife of Wykeham H. Lydall, L.R.C.P.Ed., of a daughter.

Mackesy.—On the 6th inst., at Waterford, the wife of G. I. Mackesy, M.B., of a daughter.

Waterworth.—On the 2nd inst., the wife of T. H. Waterworth, M.D., of the New Kent-road, of a daughter.

Wilbe.—On the 30th ult., at York Lodge, Finchley-road, the wife of Richard Haydock Wilbe, M.D., of a son.

MARRIAGES.

Hughes—Dixon.—On the 20th ult., at St. Mary's, Andover, Wm. P. Hughes, M.D., to Fanny Jane, widow of H. M. Dixon, M.D.

Wilson—Cowan.—On the 7th inst., at Mount-street, Aberdeen, John S. Wilson, M.R.C.S.E., L.R.C.P.Ed., F.R.G.S., of Greenock, to Isabella Henderson, daughter of Wm. Cowan, Esq., Locomotive Superintendent, Great North of Scotland Railway.

Wood—White.—On the 29th ult., at St. John's, Paddington, Henry Thorold Wood, M.R.C.S.E., to Alice, daughter of T. White, Esq.

DEATHS.

Barrett.—On the 1st inst., at Kilcullen, Co. Kildare, James M. Barrett, L.K.Q.C.P.I.

Buchanan.—On the 29th ult., at Gloucester, T. Cox Buchanan, F.R.C.S.E., aged 71.

Donovan.—On the 3rd inst., at Haddington-road, Dublin, James Donovan, M.B., retired Surgeon R.N., aged 74.

Hall.—On the 6th inst., at The Limes, Swadlincote, Christopher Hall, M.D.

Martin.—On the 3rd inst., at Pendlebury, Manchester, Thos. Martin, M.D., aged 37.

Reardon.—On the 25th ult., at Doneraile, Co. Cork, Robt. Reardon, M.D., aged 75.

Thorne.—On the 30th ult., at La Motte, St. Heliers, Jersey, James Thorne, M.R.C.S.E., L.R.C.P.Ed., in his 31st year.

Tothill.—On the 2nd inst., at Westbury, Gloucestershire, Wm. Tothill, Surgeon, aged 91.

Webster.—On the 1st inst., at York-parade, Northampton, J. H. Webster, M.D., aged 60.

[N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*]

Notes, Short Comments, and Answers to Correspondents.

THE LANCET COMMISSION ON LUNATIC ASYLUMS.

The Report of The Lancet Sanitary Commission on Hanwell Lunatic Asylum will appear next week.

Embolism of Fat after Fracture of Bones.

Obstruction of lung capillaries by fat has been found at post-mortem examinations, though injection of pure oil into the veins of animals cannot, as it appears from experiments of F. Busch and Bergmann in Dorpat, set up inflammatory action and formation of abscess. Busch, however, succeeded in some experiments conducted in Recklinghausen's Pathological Institute, in causing embolism and sudden death by rough handling of broken bones, and in proving that from the fractured spot particles of bone-marrow had been sucked into the torn veins, and carried on into the vessels of the lungs. Dr. Czeray, Professor of Clinical Surgery in the University of Freiburg, gives in the *Berl. Klin. Wochens.*, No. 44, the history of a case in which a healthy, robust mason, aged thirty-two, had his right thigh-bone broken, and died thirty-eight hours after this uncomplicated fracture with symptoms of acute obstructions in the lungs and brain. The autopsy showed a large extravasation of blood around the fractured bone-ends, in which great quantities of coagulated fat-drops could be seen floating. The broken surfaces appeared jagged on a fine splinter still connected with the periosteum. The smaller arteries and capillaries of the lungs appeared under the microscope distended with clear liquid fat throughout all parts of both organs, the right one being perhaps more filled with fat than the left. Boiling in ether drew the fat off. The endothels of the lung-cells of such pieces appeared richer in protoplasm, and their nuclei more distinct than in the normal state. In the smaller branches of the pulmonary artery quantities of coagula were found, which showed, microscopically, distinct fat-drops mixed with water. The same could be detected in the blood drawn from the femoral vein by means of a pipette. The brain showed on sectional surfaces numerous blood-spots in the cortical substance, some small, and at some places sufficiently numerous hæmorrhagic ecchymoses; the vessels leading to them were found under the microscope filled with branching emboli of fat. In the kidneys the vessels of the glomeruli were filled with fat. In the liver numerous small drops in the intra-lobular vessels could be seen, but no branching thrombus. No embolism was detected in the muscle of the heart. The filling of the lung vessels was of such extent that the obstruction of circulation, œdema, and carbonic-acid poisoning caused by it fully accounted for the sudden death, which might have been accelerated, as Dr. Czeray seems to infer, by the embolism of the brain. He thinks that cases of so-called traumatic delirium or reputed commotio cerebri may be caused by fat embolism after fractures. The pressure of the arterial blood flowing from lacerated vessels and the contractions of muscles may force the fat particles into the opened veins. Dr. Czeray contends, however, that a certain amount of fat embolism occurs with every fracture, and is easily overcome. As the melting point of human fat is as low as from 15° to 25° C., a febrile rise of the temperature of the body cannot cause any remelting of coagulated extravasations of marrow. Experiments on dogs to emulsionate injected fat by an after injection of a weak solution (two per cent.) of carbonate of soda always resulted in the death of the animals.

Mr. W. Stirling Anderson.—It shall be published very soon.

The School Board and the Darwinian Theory.

To the Editor of The Lancet.

Sir,—It would appear that the School Board for London, or at least a majority of that body, are believers in the theory that "the fittest survive," to judge from the way in which the children under their rule are, in spite of the present inclement weather, daily turned out from the hot school-rooms into the open air.

A mother, whose name I give in confidence, as she dreads being embroiled with the Board, quite recently sent her children to school, and, as they had some distance to go, gave them their dinner to take with them. On their return home in the evening, she asked them where they had eaten it, and they said in the playground. They would not be allowed to remain in the school-room during the dinner hour. As a natural consequence, these children have caught severe colds.

The same person also informed me that on two different occasions her little boy had required "to leave the room," but had been refused permission by the teacher. As can be imagined, the result was unpleasant.

Surely School Board teachers are not so obtuse as not to be able to discriminate between a child who really requires, and one who pretends to want, to go outside; or, if so, the sooner the poor little ones are confided to the care of others not so insensible to the wants of juvenile humanity the better.

Your obedient servant,

Old Kent-road, Dec. 7th, 1875. W. F. Greene, M.B., M.A., &c.

Mr. C. Cleaver.—The best work on Impediment of Speech is, we believe, by Hunt, and published by Longmans. Mr. John Bishop has written on "Articulate Sounds, and on the Cause and Cure of Impediments of Speech," published by Churchill.

Injustice to Medical Witnesses in Police Courts.

We lately published a case in which a medical witness received very inadequate remuneration in a Police Court. Mr. J. T. Williams, Barrow-in-Furness, complains to us of a still greater injustice. He, on request, attended the magistrate's court, and was kept waiting an hour and a half, and, because the case was dealt with summarily, was told that there was no fund out of which he could be paid a fee. He applied to the Home Office, and received that ample-margined letter, or rather two, to the effect that Mr. Secretary Cross was unable to order any fee to be paid. Strange injustice goes on under the forms of law. Our correspondent should decline to attend in future without being subpœnaed.

A. K. C.—Our correspondent is the best judge in such a question.

The Residence Condition of British Medical Graduation.

To the Editor of The Lancet.

Sir,—Whilst commending the leading article in a late number of your journal upon the sale of foreign degrees to men who have neither knowledge nor fitness in any way to hold them, and indeed to those who have passed through no curriculum at all, and who have given no proof of their competency to undertake the onerous and responsible duties which they assume to fulfil, I wish through you to bring home to the authorities in this kingdom another and most important phase of this question.

How is it that the registered practitioners of this country are hopelessly and for ever excluded from all possibility of obtaining degrees at home by an iniquitous combination on the part of the Universities to exact the residence clauses from men of five, ten, fifteen, or twenty years' standing in the profession? Such requirement, in plain language, simply means robbery and ruin to the registered practitioner who seeks such honours. For what man of any standing could leave his practice for one or two years without being both robbed in the price of his degree and ruined in his prospects in life? The attitude of our Universities to these hard-working men is simply disgraceful. Practically it is this: Our degrees are reserved for youths, whose time is of so little value that they can employ it in no better way than in too many cases in a useless residence, whose experience is nil, and whose theoretical knowledge may have been got up for the occasion, to vanish again as quickly. If men of position and ripened knowledge need degrees, they must submit to insult, robbery, and ruin; and by sacrificing their positions, which have cost large sums of money and half a life's labour to acquire, they may have them; and after this, as a practical and experienced man I doubt whether these Universities would extend a helping hand to their unfortunate graduates who were perishing with hunger beneath their windows. Such is life. Degrees at the price of ruin are to be despised and shunned, and hence the rapid increase of foreign ones. People cannot be expected to give £5 for a pennyworth of apples. I cannot get even £1 or 10*s.* for a 2*s.* 6*d.* bottle of medicine. The principle is the same. If the Universities of Great Britain cannot take other qualifications, position, and standing, say of five or ten years, in place of their residence clauses, and trust to examination alone in the case of such men, they ought to be disfranchised and superseded by those who can.

Take my own case, which is a type of hundreds more. I hold the three London qualifications; I have been nearly twenty years in practice; my character is unstained; my means ample to sustain the dignity of any degree; and my knowledge, theoretical and practical, would far surpass that of any youth turned out of any University, and yet no degree can I have without being ruined. Hundreds of us must seek degrees from abroad, and stand upon our legal rights. Once upon the Medical Register, upon any other qualification we can assume the foreign degrees in the face of the Medical Council with impunity; they can do nothing, since we have complied with all required of us by law in being placed upon that Register.

If you wish to avoid foreign degrees, abolish the residence clauses of Universities at home in the case of registered medical men of five years' standing, throw open the examinations to such men, and a national stimulus will be given men to work, general good will be done, and foreign degrees will be very little heard of.

Yours &c.,

November, 1875. Omega.

M.D.—The question was one of urgency, not turning upon the wages, or their relation to the weekly wages of the agricultural class—a question of starvation and of life and death. We maintain that there is decided absurdity in not giving absolute powers of medical relief in such a case to the medical officer.

Mr. Morgan.—It would be contrary to our custom to make such an announcement, except under very special circumstances.

The Registrar-General and the Nomenclature of Diseases.

To the Editor of The Lancet.

Sir,—It would probably be interesting to many of your readers besides myself to know the evidence and the authority upon which it is stated "that the sixteen deaths (since July 17th), attributed to small-pox in London, have all been fatal cases of *varicella.*" A similar statement was made in the Registrar-General's Return some weeks ago with reference to an isolated case of death from small-pox appearing in that week's Return, and it surprised me that the medical man (who must have been able to identify himself as having certified it) did not attempt to justify his diagnosis.

I am, Sir, your obedient servant,

W. W. Leadam, M.D.

Gloucester-terrace, Hyde-park, Nov. 27th, 1875.

⁂ The Registrar-General, in his classification of diseases, is under the necessity of condensing the thousand diseases enumerated in the nosology of the College of Physicians, and accordingly they are returned under rather more than a hundred headings in the publications of the Registrar-General. In this condensed classification, deaths from varicella have been returned under the same heading as those from variola. Hence the sixteen fatal cases of varicella in London between the 17th July and the 27th November were classed with small-pox, and it became necessary to explain that they were deaths from varicella. We are informed that after the end of this year deaths from varicella will be classed with "other zymotic diseases," instead of with small-pox, as hitherto.—Ed. L.

OPHTHALMOLOGY.

A DEBATE of great interest to oculists is now going on before the Academy of Medicine of Paris. On the one hand, it is contended that alterations of vision, such as strabismus, myopia, &c., are owing, according to one camp (M. Jules Guérin at the head), to muscular retraction. He considers the disturbance of sight as an effect or consequence of the retraction of the muscles of the eye, just as club-foot is the consequence of the retraction of the muscles of the leg. M. Guérin thus maintains that strabismus is, to use his own forcible expression, the club-foot of the eye. (It should be noted that M. Guérin has been for many years a distinguished orthopædist.) His adversaries (M. Giraud-Teulon, a scientific ophthalmologist, at the head) contend, physiologically, that in the phenomena of accommodation there is neither change of curve in the cornea or in the connexions of the lens, nor alteration in the muscles of the eye. They, in fact, hold that the phenomena are owing to changes of form of the surfaces of the lens, which changes depend on the contraction of the ciliary muscle. They consider myopia and strabismus, etiologically, as the expression and the result of certain changes in refraction. M. Guérin answers that these changes of refraction are secondary effects of strabismus and myopia, and that both are dependent on muscular retraction. Again, M. Giraud-Teulon's school consider, pathologically, myopia, amblyopia, astigmatism, &c., as distinct and separate entities; whilst their opponents say that these anomalies are all connected together, and may simply be explained by muscular retraction. Practically, says M. Guérin, modern oculists have no resource but glasses; whilst he relies on the division of the retracted muscles. Thus we have, on the one hand, oculists and opticians; and, on the other, physiologists and surgeons. M. Guérin considers himself as the leader of the latter.

Captain Bedford Pim.—We cannot exchange.

PRESERVATION OF VACCINE LYMPH IN CAPILLARY TUBES.

To the Editor of THE LANCET.

SIR,—Of the different methods of storing vaccine lymph, that of Dr. Husband in his capillary tubes is for many purposes, especially the revaccination of large numbers of people, undoubtedly the best; but in my hands it is subject to the one great objection, that occasionally after filling a tube you are unable to blow out the contents; and I wish to ask my brother vaccinators, through the medium of your widespread and influential journal, whether they have ever met with the same result, and are able to offer an explanation of its cause.

Dr. Husband, in his Instructions for the use of his tubes, states that "if you delay the sealing process too long, more than five or ten minutes perhaps, the lymph within the tube is apt from evaporation to become adherent, especially if it be more than ordinarily viscid, and it cannot afterwards be blown out"; but the coagulation to which I refer is not due to delay in the sealing, for it takes place instantly. I have long been in the habit, in arm-to-arm vaccinations at my station, of picking up the lymph from the opened vesicles by means of a tube, and then blowing it out on to the lancet; my reasons for adopting this plan being that by so doing you get the lymph perfectly pure, free from epithelial scales, pus-globules, or blood-discs; you avoid all tearing of the vesicles; and you are able to collect lymph from several different vesicles if the supply be small, a matter of great difficulty with a lancet; and this setting in the tube takes place in the few seconds that elapse between the picking up and blowing out, and consequently before the application of any heat to seal the ends. I have found this coagulation occur most frequently in lymph collected from typical vesicles—viz., those free from areolæ on the eight day, or from those somewhat retarded in their development. It is not nearly so frequent if the vesicles be full and plump, or the arm slightly inflamed; doubtless, because in the latter case the lymph is more limpid. By taking a tube that has set as above described, and breaking off an end so as just to include a small portion of the contents, you can draw out a fine thread or hair of coagulated lymph or serum; the remainder can then be blown out, and by using this for vaccination you generally (although not with certainty) obtain good results. I have microscopically examined several of these threads, and in *every case at present* found a minute trace of blood, possibly only three or four blood-discs, invisible to the naked eye, and never suspected until revealed by the microscope—for, of course, all visible blood is carefully avoided; and I think that this may offer the explanation that the coagulation is due to the serum of the blood inadvertently taken up.

I remain, Sir, yours truly,

Greenwich, Nov. 29th, 1875. J. P. PURVIS, Public Vaccinator.

J. H. B.—1. Bradbury and Evans, Whitefriars; or Chambers, Paternoster-row.—2. Nothing recent.—3. Churchill, New Burlington-street.

Mr. Mayer.—We fear our correspondent attaches an undue importance to the matter.

THE CORPUS LUTEUM.

To the Editor of THE LANCET.

SIR,—Allow me to say a few words on the corpus luteum. In the casebook of the Bristol Asylum I found the following details entered by my distinguished predecessor, Dr. Benham:—"Patient, A. B., epileptic, admitted before the age of puberty; died during menstruation, a considerable time after. At the post-mortem her hymen was found entire, and a perfect corpus luteum in one of her ovaries." In 1851 Dr. Letheby read a paper before the Royal Society, in which he described two cases in every respect similar to the one recorded by Dr. Benham. Many years ago in Edinburgh a lamp-lighter killed his childless wife, and in her ovary a true corpus luteum was found. From these four interesting cases I infer that true corpora lutea are found in the ovaries of both impregnated women and virgins, but oftener in the former than in the latter; that when found in the virgins they have died menstruating; and that at present we are as ignorant as to the cause which produces at one time a true and at another a false corpus luteum, as we are of what produces at one time a male and at another a female child.

Yours faithfully,

HANMER DICKSON,
Late Assistant Medical Superintendent,
Nelson-square, S.E., Dec. 2nd, 1875. Bristol Asylum.

"EARTH TO EARTH."

A NEW kind of receptacle for the dead has been introduced by the London Necropolis Company. The object had in view in its construction is the same as that contemplated by Mr. Seymour Haden in his suggestion of the use of wicker-work—viz., to hasten dissolution. The new coffins are made of compressed pulp, held together by wooden fillets, look very much like ordinary coffins, and are as substantial till consigned to the earth. Then a change rapidly ensues, the damp soon affecting the pulp, which softens and falls away, leaving the earth to act upon the body.

Mrs. A. M. Nolan (Preston) will perceive that her subject has received attention.

THE SANITARY ASPECTS OF THE SACRAMENTS.

To the Editor of THE LANCET.

SIR,—The laws of health are necessary to the well-being of mankind in all the relations of life, and there is no station too exalted and no office too sacred to be independent of these laws.

With this exordium I desire to point out to the medical profession the duty that devolves upon them to instruct the church in sanitary matters. Already much has been accomplished in respect of burial of the dead; but there is one subject that laymen shrink from discussing—viz., the sanitary aspects of the sacraments, especially of the supper. Practitioners of medicine may well object to the early appearance at church of a woman and her infant, through which cause many lives are lost, still they have the power to restrain their patients from precipitancy of action; but as respects the other sacrament they are powerless.

The sanitary evil that ought to be abated is the use in common of one cup. There is danger in this use of communication of mouth disease. The usages of society would have long since swept away this common use of one vessel but for the dread that man feels for meddling with sacred rites.

I reiterate "there is no office too sacred to be independent of the laws of health."

I am, Sir, your obedient servant,

Rochester, Dec. 4th, 1875. FREDERICK JAMES BROWN, M.D.

Alpha.—The matter should admit of the most complete and easy adjustment. A. having practically declined to go, as requested, to see his patient, B. was perfectly right in going. B. would have done well to have taken an early opportunity of seeing A. to explain and receive explanations; but neither his not doing so nor his taking charge of the case gives any justification of the words used by A., which should be simply withdrawn. Strong adjectives, such as those used by A., should be reserved for very different cases. At the same time we can readily believe that they were the expression of a temporary irritation, and not of any permanent opinion. B. is justified in asking for their withdrawal.

Mr. Adams Parker.—Very soon.

A Constant Reader, (Brussels.)—14, Cockspur-street.

A CAUTION TO GIVERS OF TESTIMONIALS.

To the Editor of THE LANCET.

SIR,—In a moment of weakness I unfortunately wrote a letter on behalf of an old pupil at King's College, whom I remembered years ago as a respectable person, and who assured me he was in distress, mainly through the effects of an injury. This letter was granted by me for the express purpose of an application to the Medical Benevolent Fund.

I find that the individual in question has made extensive use of this letter for begging purposes, and has annoyed a great number of old King's men, and my medical friends in this neighbourhood especially. I regret exceedingly that I should have been the means of this annoyance, and I take this step of writing to you for the purpose of putting them on their guard, and thus making all the reparation in my power for the annoyance I have caused them by my act of indiscretion.

Yours obediently,

Wimpole-street, December, 1875. HENRY SMITH.

Z. D. Y.—Our correspondent should, to say the least, have received intimation of the change from the patient's friends, who should have been instructed as to their duty in this matter by the family doctor. Possibly he gave such instructions.

IMPROVED TRUSS.

To the Editor of THE LANCET.

SIR,—In your journal of to-day's date, under the heading of "New Inventions," appears an improved truss with ball-and-socket joint, which allows the pad to be placed in any position. We beg to say that neither principle nor general construction of the truss referred is *new*. The *ball-and-socket* principle, with screw adjustment to fix the pad at any angle, was patented on the 28th of August, 1874, No. 2947, and we purchased the patent right of the said inventor. At the Leeds Exhibition this year one of the trusses referred to has been exhibited by us. We likewise enclose the patent specification for your inspection, in which you will find the *ball-and-socket* principle, which can be fixed at any angle, is claimed by the inventor.

We much regret having to trespass on your valuable space; but can scarcely allow the truss to be called a new invention, the same having been anticipated at least fifteen months ago.

We remain, Sir, your obedient servants,

West Smithfield, Dec. 4th, 1875. ARNOLD AND SONS.

THE TREATMENT OF RINGWORM.

To the Editor of THE LANCET.

SIR,—I beg to inform Dr. Welsh, through the medium of your columns, that I have at present a case of ringworm under my care, in which I have for five weeks persistently used iodine in the form which he recommends, but without success. I have since tried sulphur &c., and am now, by the advice of a medical friend, applying petroleum, the result of which remains to be seen.

Your obedient servant,

Claughton, Cheshire, Dec. 5th, 1875. J. FOURNESS BRICE, M.D.

ULCERATED NIPPLES.

M. LEGROUX (*Annales de Gynécologie*, Nov. 1875) advises the following treatment:—Spread with a camel-hair brush a layer of elastic collodion around the nipple, in a radius of an inch or more; a piece of gold-beater's skin should then be placed over the nipple and collodion, taking care to make a few holes with a pin over the part of the gold-beater's skin which covers the nipple, so as to allow the milk to ooze through. No collodion should be spread on the nipple itself, as some pain might thereby be occasioned. By the rapid evaporation of the ether the collodion dries up, and the gold-beater's skin adheres. The nipple is then more or less pressed down by the latter, which in drying becomes tense. When the child is to be nursed, the end of the nipple should be wetted with a little water. The gold-beater's skin which covers it becomes soft and supple, allows the nipple to swell, and protects the ulcers and fissures from the strain of suction. The mother or wet-nurse thus suffers no pain, and the ulcers heal in a few days.

THE paper of *Mr. S. J. Knott* shall be published at a very early date.

Mr. Nankivell is thanked.

A CORRECTION.

To the Editor of THE LANCET.

SIR,—Pray allow me to correct two important errors in your report of the proceedings of the Medical Society of London in the last number of your journal, p. 804. I did not say, as reported, "that worms were never introduced into the system by vegetables." I said that tapeworms in man were never so introduced, the author of the paper, Dr. Brunton, having stated "that they sometimes were." In the epidemic sore-throat the glands of the "*back*" of the neck were never affected, as stated in your journal.

Yours obediently,

Beaufort-street, Chelsea, Dec. 6th, 1875. EDWARDS CRISP.

J. A.—The subject has been noticed before. Our correspondent should refer the circular to the Bodies whose diplomas the person in question holds, and ask them if they can do anything in the matter. We shall be glad to have the replies.

TROUSSEAU'S COMPRESSOR.

To the Editor of THE LANCET.

SIR,—I was much interested in the report of the surgical cases in the Cashel Union, described by Mr. Laffan in your last issue. Would you allow me space to ask him where "Trousseau's compressor" may be obtained.

I am, Sir, yours &c.,

Liverpool, Dec. 3rd, 1875. W. MACFIE CAMPBELL, M.D.

COMMUNICATIONS not noticed in the current number will receive attention in our issue of the ensuing week.

COMMUNICATIONS, LETTERS, &c., have been received from—Sir H. Thompson, London; Prof. Attfield, London; Mr. H. Smith, London; Mr. C. A Clinical Lecture

ON

THE BEST MANNER OF EMPLOYING INSTRUMENTS IN CASES OF STRICTURE WHERE MUCH DIFFICULTY EXISTS.

Delivered at University College Hospital on November 25th, 1875.

By Sir HENRY THOMPSON,

SURGEON EXTRAORDINARY TO H.M. THE KING OF THE BELGIANS; EMERITUS PROFESSOR OF CLINICAL SURGERY IN UNIVERSITY COLLEGE HOSPITAL.

(*Reported by* Mr. G. Buckston Browne.)

I have now to consider the question, How are you to deal with a case of stricture of the urethra in which real difficulty exists in passing an instrument into the bladder? Let a case be supposed in which attempts have been made, perhaps by several hands, and hitherto without success.

First, let me point out in what the chief mechanical difficulties in such a case might consist. There are four:—

1. Extreme narrowness of the stricture.
2. The stricture may be tortuous.
3. It may be complicated with false passages.
4. The urethra behind the stricture may be irregularly dilated and reticulated.

Difficulties of another kind, not mechanical, are frequently met with; these are two in number, and are to be considered hereafter—viz., (1) the stricture may be very resilient, and liable to become narrower, and to produce absolute retention on any instrumental contact; and (2) any use of the instrument may produce in the patient an attack of rigors.

1. Let us consider first the mechanical causes of difficulty, of which the first is extreme narrowness.

In regard to this, the first thing you must do is to see the patient make water. The failures to pass the instrument may not necessarily have arisen from narrowing of the urethra or from tortuosity; there may be a false passage in the canal. It may, indeed, be that there is no stricture at all. No greater mistakes are made than those which occur with patients who have little or no stricture, either from the surgeon not knowing well how to pass the instrument, or from there being a false passage into which it enters, so that it does not reach the bladder at all. You are first, then, to see the stream of water, perhaps on more than one occasion, so as to estimate it fairly, and you will judge by that what size of instrument is to be used. And always let the instrument correspond with the size of the stream which you see; but it should correspond only in this way—the instrument should be a little smaller. You will sometimes see a patient who scarcely passes a stream at all; the urine issues only in a succession of drops. This being his constant, and not a temporary or accidental, condition, how very small must be the instrument which is adapted in size to traverse fairly the stricture.

The first step to be taken with such a case, after having ascertained, as I assume to have been done, the situation of the stricture, is to introduce very gently the smallest English gum catheter without a stylet, and try to insinuate it through the obstruction. For this purpose I have endeavoured to obtain some exceedingly small instruments, much smaller than any hitherto made.* This tiny catheter, which I show you, containing a slender steel thread rather than a stylet, may be used either with or without it. The value of this little instrument, after its extreme tenuity, is its ability to transmit a drop of urine through its interior, and so assure you of its position when the bladder has been reached, an assurance, I need hardly tell you, of great importance. It is worth while making a careful and somewhat prolonged trial, and if you succeed, the instrument is to be tied in at once and the route secured. If I fail with this, I then try a silver catheter of the smallest size.

But there is one very important matter in relation to the silver instrument—namely, that it is an extremely dangerous one in inexperienced or in incautious hands. Nothing is easier than to implicate its slender point in a lacuna, and if the slightest force be used, the point leaves the route and finds a track among the loose tissues outside the urethral mucous membrane, and thus a false passage is commenced. If you cannot train your hand to employ it with extreme lightness and delicacy, by no means use it. It should be held and moved with so much tenderness, that if the point meets with any resistance in its course, the fingers rather should slip down the shaft than communicate pressure to the instrument. Any kind of force in its use is not to be thought of—its only value is in its capacity for being insinuated between closely applied surfaces, and any sense of opposition to its point is a clear intimation that its route may lie right or left, but not straight on. It is not fit for the hand of a tyro, but when he is habituated to the use of somewhat larger instruments, the ability to use this will follow. A careful trial, however, with the very small gum catheter, first without and then with the stylet, will in many cases make this unnecessary; but these failing, I know no instrument so valuable as a very fine silver one with a little increase of size in the shaft, to render it steady. The final three inches should not exceed half the size of No. 1 of the English scale; the shaft should gradually rise to fully No. 2.

2. A stricture may be more or less tortuous; in other words, it does not necessarily follow the exact direction of the urethra.

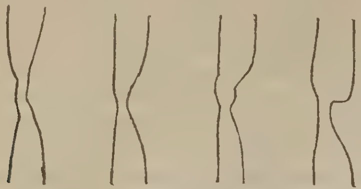
It may be a little on this side of the axis or on that, not necessarily in the middle. You may see this sometimes in the dead body; and you may infer it from experience on the living. When you have to deal with a very narrow or with a tortuous stricture, there are two quite distinct systems of using an instrument, either of which you may employ. What I have to say, then, applies to the manipulation necessary in all cases of difficulty under the present and preceding heads; and I have reserved it therefore until now. First, the little instrument employed, whatever its nature, may be applied by what may be called "groping"—that is, by carrying the point in any and every direction, with the utmost care of course, until by chance it has entered into the stricture, as you may feel by the sensation of the point being "held" or "grasped." For this purpose very slender solid instruments are made of gum-elastic, of catgut covered or not with gum, or of whalebone, since these can be produced of rather smaller size than the hollow instruments which I have just described. In order to add to the chance, as is supposed, of finding the orifice, there are some of the first-named material, the ends of which are formed somewhat into the shape of a corkscrew, or are otherwise made to deviate from a straight line. All these are of French design and workmanship, but none have the advantage of being hollow, to demonstrate their presence in the bladder when they arrive there.

Now, I advise you not to rely on mere groping to find the orifice; it is exceedingly dull, mechanical work to be constantly groping for a considerable time on the chance of success.

There is a method of search, however, conducted on a fixed principle, which I much prefer and always employ. I advise you to adopt that, or any other you can devise, provided that it be a systematic one, and also an exhaustive manner of making the necessary exploration and researches for the orifice of the stricture. Some of you have often seen me apply it to patients in the wards upstairs. According to this manner you proceed systematically and examine each side of the urethra *seriatim*. We will suppose the urethra to require examination on four sides—a roof, a floor, a right side, and a left side. You are to take your slender silver catheter and slide its point delicately along each side successively from the orifice to the place of obstruction. If the orifice of the stricture is not *exactly* in the middle line, and we may fairly believe that it rarely is so, then there is one side of the passage which will more easily lead into the narrow way than any other. These diagrams will show what I mean. If I go down on this side I shall probably not get into the stricture; but if I slide down gradually on the other I shall probably get the instrument in, because you see there is less obstruction on that side. Begin, then, by the roof. The roof is the firmest part, the least likely to furnish obstruction in the way of ducts or lacunæ, and by following it you will be most likely to carry the point in. The floor, on the contrary, is the softest, loosest, and most spongy part, and will be most likely to yield to the instrument and give way. If your first effort does not succeed, take the right side; if that does not do, take the left; if that fails, try the floor. If you are very careful you may make the attempt in this manner for thirty or forty minutes without doing any damage; but if the patient suffers, or if he bleeds, or if you are losing patience, give up the task, or you may make a false passage, and increase the difficulty considerably.

---

* Messrs. Weiss and Son have taken great pains to accomplish this for me, and have produced some slender delicate instruments much smaller than No. 1, which have been of great service.



3. The existence of a false passage leading out of the urethra is another serious obstacle to the introduction of instruments into the bladder.

The principle which must guide your action here is to be very careful to avoid the side on which the false passage is. A false passage commences usually on the floor, and no doubt for a reason already mentioned—viz., the fact of the structures below being looser and more delicate than those above. When you examine a patient with a false passage, you may find the instrument passing to its very end, notwithstanding which no urine flows. Hence the false notion of stricture at the neck of the bladder. When the instrument has thus passed, put your finger into the rectum, and you will know instantly whether there is a false passage; for, if so, there are only the coats of the bowel, which are very thin, between your finger and the instrument, so that you feel it very distinctly; and very commonly not in the middle line, but rather to the right or to the left. But if the instrument is in the right passage, the whole thickness of the prostate, not always very considerable, is felt between it and your finger. It is almost always in the bulbous portion that the instrument leaves the urethra and gets under the prostate. What you are to do, then, is to withdraw the catheter two inches or so, pass it on again, keeping as close along the upper part of the urethra as you can, ascertaining by means of the finger in the bowel that the instrument is not passing into the old route. But when a false passage exists, it sometimes constitutes the chief obstacle to the introduction of an instrument, for, as I have before hinted, the stricture itself may be only inconsiderable. The size of the stream will help to determine this point; and if, so far from being a mere thread it has a volume equal to a No. 6 or 7 catheter, use a No. 5 silver one, so that you can guide it, and try each side of the urethra successively until you discover which it is that enables you to clear the orifice of the false passage. Remember the result, and you have a key to the difficulty which will enable you to overcome it with ease on the next occasion.

4. Difficulty presented by dilatation and reticulation of the urethra behind the stricture.

Suppose next, that, following these hints, you have carried the instrument through the stricture; there is a sort of grasp felt on attempting to move the instrument which is quite unmistakable. But that very "grasp," which you are so satisfied to feel, makes it less easy to manipulate the point of the catheter after it is through the stricture, and you may have a source of danger to encounter in the urethra beyond. Thus the mucous membrane, being sometimes reticulated from the presence of dilated lacunæ, it is easy to engage the point of the instrument in one of these, and make a false passage. Besides this, as the result of long continued fluid pressure and straining, the urethra behind the stricture is occasionally much dilated, and the whole surface is so irregular that it requires care and an acquaintance with this condition to traverse it safely. Here especially, with a small instrument already firmly grasped, you may require all the caution you can command in completing its safe course into the bladder.

The consideration of the difficulties which are not mechanical must be deferred to another meeting.

ON EXCISION OF THE ANKLE.*

By JAMES F. WEST, F.R.C.S.,

SENIOR SURGEON TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

Excision of the ankle, although admitted to be of the highest value in gunshot fractures of the bones implicating the tibio-tarsal articulation, and also to be very suitable in severe cases of compound dislocation of the ankle, has not hitherto been regarded with much favour for chronic disease of that joint.

Resection has probably been less frequently performed of this than of any of the other joints. Objections have been made to it on various grounds. Prejudice against the operation has been entertained and freely expressed by some, who, having never performed it, have condemned it as useless, or even improper, for chronic affections of the ankle-joint. Thus Holmes, in the first edition of his System of Surgery, spoke disparagingly of the operation, having never done it; but in his second edition he says—"my individual experience, though limited to two cases, which recovered very rapidly, has been very satisfactory. ...... I believe it is very advisable and advantageous in appropriate cases." And again he says in another place—"In cases of successful excision the limb is very much superior in usefulness to any stump which can be formed, whether by Syme's or any other method of amputation." Others who have had one or two unfortunate cases have been deterred from performing resection again, forgetting that almost always the early days of any operation are beset with obstacles and disappointments. On the other hand, those who, like Hancock, Langenbeck, Lee, and Heyfelder, have given it a fair trial have been rewarded with excellent results; and their success ought, I think, to establish it for ever as one of the most legitimate resection of joints which surgery has at its command.

Resection of the ankle, or, in fact, of any other joint, is of course not justifiable until attempts have been made to remedy the joint-mischief by all the means at our disposal. Rest; immobilisation; counter-irritation, by blisters, iodine, or by the actual cautery; and, lastly, free incision into the joint and removal, if possible, of any fragments of loose necrosed bone,—must each, in succession, have been resorted to; while at the same time the patient's general condition has been to the utmost improved by fresh air, good living, and such tonics as iron, quinine, and cod-liver oil.

Still, after the adoption of all these measures, suppuration in and about the joint, pulpy degeneration of synovial membrane, ulceration of cartilage, and caries of the cancellous structure of the bones, will in some cases continue, and then arises the question, Shall the leg be amputated by Syme's or Pirogoff's method, or shall the patient have the chance first offered to him of keeping his foot, even although this will necessitate a somewhat difficult and tedious operation and a protracted convalescence?

I entertain a strong opinion that by adopting Ollier's (of Lyons) mode of subperiosteal resection, the future history of excision of the ankle will be far more satisfactory than the past has been. Experience has also shown that partial resections had better be given up, and that it is better to excise the entire joint than to limit the operation to the removal of the obviously diseased portions of it. Attention to the following measures during the after-treatment will also add greatly to the number of successful cases:—1. Early and complete immobilisation of the limb. 2. The use of the anterior iron bracketed splint, by means of which, as after resections of the knee, the leg can be suspended in a Salter's swing, and the lateral openings formed in the joint dressed without much disturbance of the parts. Lastly, the employment of drainage-tubes, passed from one side of the ankle to the other, by which pus and carious débris may be removed, and through which the wound may be daily washed out by some weak disinfecting solution, as carbolic acid or Condy's fluid.

---

* A paper read before the Birmingham and Midland Counties Branch of the British Medical Association.

The originator of resections, as of so many things that still hold good in surgery, was Celsus, as we learn from this passage: "Ideo quod excedit, abscindendum est." But the first to apply this principle to the ankle was an English provincial surgeon, Hey, of Leeds, who in 1766 resected the lower ends of the tibia and fibula for compound dislocation; and since that time resection of the ankle has frequently been performed under similar circumstances with such good results that few would question the propriety of performing resection for compound dislocation of that joint, rather than of at once recommending amputation of the leg. Hey's success led to the adoption of the operation for chronic articular disease by Moreau, and in 1792 he first removed the lower ends of tibia and fibula for disease.

It is perhaps advisable to recall the names of those who have performed the operation, and who have expressed their opinion in favour of it, before calling attention to the case which I intend to bring under notice, and which I hope and believe will induce many other surgeons to give it a trial in any suitable case they may have under their care.

Mr. Hancock, in his lectures at the Royal College of Surgeons in 1867, referred to 19 successful cases of his own, and mentioned that Heyfelder had given 26 examples of this operation, of which 5 died, 1 suffered consecutive amputation, and the rest proved successful; and that of Jaeger's 24 cases 23 proved successful and only 1 died.*

Mr. Stokes, in the *Dublin Quarterly Review* of 1870 enumerates 51 cases of resection of this joint, with good results in 38. No doubt many of these operations were performed for traumatic injuries, and objection may be taken to them on that account; but, on the other hand, numerous cases may be found in the medical journals of the past few years, and in the works of recent surgical writers, in which resection has been performed for chronic articular disease with admirable results. Thus, in March, 1870, Mr. Erichsen excised the ankle of a woman, aged twenty-eight, for scrofulous disease of the ankle, removing at the same time part of the os calcis, with success.

In December, 1870, Dr. Watson showed at the Medico-Chirurgical Society of Edinburgh a boy from whose right foot he had some months previously excised the astragalus and the ends of the tibia and fibula. The result was remarkably good, the patient being able to stand on the foot, having considerable power of flexion and extension, and the limb not being shortened more than half an inch.

In THE LANCET for Jan. 20th, 1872, is a case of excision of the ankle by Mr. Canton, performed at Charing-cross Hospital on Dec. 9th, 1871, on a man, aged thirty-one, who had had chronic disease of the joint for eight years. The man's progress is said to have been "highly satisfactory, and at no time had there been any constitutional symptoms."

In the *British Medical Journal* of Sept. 7th, 1872, Mr. Sydney Jones records the case of a boy aged fifteen, whose ankle was excised for articular caries on Jan. 24th. The limb was not taken off the splint for two months, and "there was then firm bony union, and the line of the foot with the leg was very good."

Chassaignac† performed resection of the ankle on a woman aged twenty-three for chronic suppuration in the joint and necrosis of the fibula, in whom there was such "extreme mobility of the foot that it was only held in place by the skin and by the tendons, which were in part exposed," and yet after two months a good recovery occurred.

Ollier, of Lyons, relates a case of resection for comminuted fracture of the bones of the ankle, which seems to surpass all the others on record, for in that instance there was so much reproduction of bone that the patient could walk ten miles, and even dance.

Sédillot, in a memoir read before the Academy of Sciences in 1867, also speaks highly of his experience of this operation.

Lastly, in Jan. 1874, and again in May, 1875, Mr. Henry Lee brought the subject of resection of the ankle forward at the Medico-Chirurgical Society of London, and after relating his own experience, which was highly in favour of it, a discussion ensued, in which Messrs. MacCormac, Maunder, and others joined, and most of them had a good report to give of the operation.

I will now briefly narrate a case in my practice, and then call attention to the mode of operating which I prefer, and to the advantages which resection offers.

Alfred C——, aged sixteen, a stable-boy, was admitted into the Queen's Hospital on Nov. 10th, 1873, for synovitis of the ankle-joint, followed by ostitis of the tibia and fibula. The following history was obtained:—Ten weeks previously he had sprained his ankle while jumping from a loft, a distance of ten feet. Considerable swelling followed, but not much pain, so that he was able to continue his work for a fortnight; at the end of that time he was obliged to take to his bed. Previous to admission an incision had been made into the swelling, and a large quantity of pus evacuated. He complained of great pain in the joint at night.

On admission, there was considerable swelling around the ankle, and the patient was unable to put the foot to the ground. Openings on either side of the joint discharged a large quantity of fetid pus. There was great pain on the slightest movement, and the patient could obtain but little rest at night. By means of a probe it was found that the lower ends of the fibula and tibia were necrosed to a considerable extent. The joint was immobilised by means of a gutta-percha splint, and the patient was ordered half an ounce of the iodide-of-iron mixture three times a day.

Nov. 25th.—Patient's health being remarkably good, but the purulent discharge continuing copious, chloroform was administered, the actual cautery applied to the surface, and subsequently a drainage-tube passed right through the joint.

Dec. 20th.—The lad's general health being good, and the case seeming favourable for resection, the operation was performed as follows:—Lateral incisions were made parallel to the tibia and fibula; the fibula was first divided with the chain saw, then the tibia with Butcher's saw, and lastly the astragalus with Hey's saw. The articular surfaces of all the bones were found to be devoid of cartilage and superficially necrosed. The operation was performed by Ollier's subperiosteal method, and, Esmarch's bandage having been used, it was quite bloodless. No tendons were divided. A drainage-tube was inserted between the bones of the leg and foot, and the limb at once immobilised with bandages and a gutta-percha splint. Chloroform was used, and well borne by the patient.

28th.—A week after the operation it was noticed that there was free discharge, and that the patient's condition was very good. An anterior splint and swing apparatus (Salter's) were employed. A fresh drainage-tube was passed through from one side of the joint to the other, and he was ordered one ounce of quinine mixture three times a day.

Jan. 22nd.—Less discharge; limb comfortable; eats and sleeps well. Carbolic acid lotion used for dressing, as the discharge is fetid.

Feb. 2nd.—Granulations in the wound rather exuberant. Red lotion to be used, and pressure made by means of a piece of sheet lead around the ankle.

March 2nd.—Wound nearly healed, and much general consolidation about the union of the bones, so that he can lift the limb easily. This was about eleven weeks after operation.

A starch bandage was subsequently applied, and it was noticed on March 23rd that the union of the bones was firmly consolidated, that the lines of incisions looked healthy, but that there was still some discharge of pus.

April 4th.—Patient left the hospital, less than four months after the operation, with the wounds discharging but little, and the shortening was then about one inch.

He is now, December, 1875, able to earn his living, and to walk four to five miles without inconvenience.*

My manner of making the incisions in this case was almost identical with that described and recommended by

---

* THE LANCET, vol. ii. 1867, p. 121.

† Opérations Chirurgicales, vol. i., p. 706.

* The patient was exhibited at the meeting on Dec. 9th, 1875; there was not more than an inch of shortening, and the bones of the leg and foot were firmly anchylosed together. Mr. Prosser, of Bromsgrove, has paid great attention to the boy, and has conduced largely to the good result

Hancock, except that the lateral incisions were not carried forwards and downwards on the tibial side as far as the projection of the inner cuneiform bone, nor on the fibular side to within half an inch of the base of the outer metatarsal bone; such free incisions are, in my opinion, rarely necessary, and further tend rather to lead to subsequent suppuration among the tarsal bones. Lateral incisions are far preferable to the semicircular incisions which I have seen employed at the Leeds Infirmary and elsewhere, inasmuch as with the former all the tendons are saved, and no vessel of importance is divided. Excision of the ankle is one of those operations in which the advantages afforded by Esmarch's bandage are most appreciated. Not only is the patient free from hæmorrhage, but in consequence of the parts not being covered with blood, we can see clearly what we are doing, and need only take away as much of either of the bones as is absolutely diseased, and if on taking one section of bone caries is still evident, we can take slice after slice of bone away until we get to sound osseous tissue, without having our view of the joint cavity in any way obstructed. The joint having been opened on the outer side and the fibula exposed, I separate the periosteum from it with the raspatory, and then cut off the lower end of that bone with the chain-saw. I prefer the chain-saw because it can readily be passed round the bone, and can be kept close to it, so as not to endanger the peronei tendons, and hence I think it presents greater advantages than Hey's or Butcher's saw. I then divide the internal lateral ligament, keeping close to the bone, so as to avoid the flexor tendons and the posterior tibial artery, push the lower end of the tibia through the fibular opening, denude the periosteum, and cut the articular surface and inner malleolus off with Butcher's saw, and lastly with Hey's saw I remove the upper part of the astragalus. Should that bone be extensively diseased it should be freely gouged, and the carious or necrosed portions cleared out with the osteotrite. In some cases it has been successfully removed entire, along with some portion of other of the tarsal bones, as in Mr. Swain's case of a boy, aged fourteen, for whom at various times he excised the ankle-joint and the bones of the tarsus for caries; but, as a rule, when more than one of the tarsal bones is largely affected with caries, it will be better to amputate at once by Syme's method. Pirogoff's operation, though recommended by some surgeons, is not, as I have before proved, suitable in such cases, in consequence of the great risk of caries recurring in the remaining portion of the os calcis.

I hold that complete resection of the joint is better than partial, and in that respect I differ from Mr. Bryant, who says, "Resection in cases of disease is very hazardous, except in partial resection of the fibula, which is generally successful." Now, having myself tried partial resection of the fibula more than once, and especially recently on a boy aged sixteen, whose disease seemed limited to that bone, and having had subsequently to submit the patient to secondary amputation, I cannot agree with Mr. Bryant's opinion, and I think he will modify it when he has had some personal experience of complete resection of the ankle, which up to the present time he admits he has not had.

Immobilisation of the limb before the patient leaves the operating-table I deem to be essential. I care very little whether that condition be obtained by a gutta-percha or leather case or by a starch or plaster of Paris bandage with suitable windows on either side of the ankle, but the immobilisation must be thorough, and the apparatus, whatever it is, should not, if it can be avoided, be disturbed for at least a couple of months. The limb may, with comfort to the patient, be suspended by one of Bartleet's or Watson's anterior splints in a Salter's swing.

As new bone is often formed rapidly in young subjects, and concomitantly there is an abundance of exudation material about the ankle, it is advisable in the course of two or three months to give support and compression to the new tissues by means of a piece of sheet lead one-eighth of an inch in thickness, retained *in situ* by careful bandaging.

Another feature of the operation of great value, to my thinking, is the preservation of the periosteum by means of careful employment of the raspatory, so as to avoid cutting that membrane. The instrument should be kept close to the bone as possible, so as to detach some of the granules along with the periosteum.

The idea of regenerating bone by this means, so generally attributed to Ollier, of Lyons, belongs, as Giraldès candidly points out in his "Mal. Chir. des Enfants," to our countryman Goodsir, who, as early as 1845, discovered the fact that by preservation of the periosteum with the subjacent and still adherent fine particles of bone new bone could be formed.

Preservation of the length of the limb and greater consolidation of the parts, both points of immense importance as regards the patient's future condition, are gained by this method of subperiosteal resection, and I cordially echo all that has been said in its favour by Professor von Langenbeck in his work "On the After-results of Joint Resections," and not less by another great authority in the treatment of diseases of joints, Dr. Sayre, of New York. Drainage-tubes applied at the time of resection, so that the joint cavity may be kept free from discharge, and thoroughly cleansed daily with some weak disinfectant solution, are small, though not unimportant, matters to be attended to in the after-treatment of the case.

Having now glanced at most of the points connected with the operation, let me, in conclusion, commend it to your consideration. It may be the means of saving a foot; it is true the foot will probably be anchylosed to the bones of the leg, but still it will prove more valuable and convenient for walking than any artificial foot that can be fitted to a stump. Sometimes there is a sort of fibrous anchylosis between the bones of the leg and foot which allows of such free movement that the patient, as in one of Ollier's cases, may walk ten miles and dance an evening through. Firm bony anchylosis is very likely to result, and there will probably be comparatively little shortening if the periosteum is left.

The chief objection that can be urged against the operation is that recovery from it is tedious and protracted, and therefore that it is more applicable for patients in the upper class of society than to those who are found in hospitals. Still this is after all not a very formidable objection; three to six months' confinement will certainly be necessary, but perhaps a patient who had submitted to amputation of the leg might be quite as long before his stump would bear the pressure of an artificial limb.

Another argument in favour of resection is that it is scarcely a more dangerous operation than amputation, either at the ankle or in the lower third of the leg; and, lastly, it has this to its credit, that should resection fail, as it sometimes does, from such patients having but little constitutional or recuperative power, we can still submit the limb to amputation as a *dernier ressort*.

Birmingham.

ON SALICYLIC ACID.

By J. C. OGILVIE WILL, M.D.,
ASSISTANT-SURGEON TO THE ABERDEEN ROYAL INFIRMARY.

Although salicylic acid has been much vaunted by continental surgeons, more especially by Thiersch and Kolbe, as superior as an antiseptic to carbolic acid, it has not, so far as I am aware, come into general use in this country, and the recent discussion at the Clinical Society will probably not do much to advance its cause. A pretty extended trial of it has, however, convinced me that in it we possess an agent of extreme value in a large class of cases; but I do not intend at present entering on a detailed account of the cases in which it is found useful, but simply to direct attention to its value as an antiseptic, to its advantages over other substances used for a like purpose, and to a few of the forms in which it may be employed, with brief notes of some cases as illustrative of its beneficial action.

Godeffroy, by a series of careful experiments, proved that salicylic acid is three times as powerful in its anti-fermentative action as carbolic acid. He used dough formed of yeast, flour, and water, to separate portions of which he added varying quantities of carbolic and salicylic acids, and noted the length of time that elapsed before fermentation took place. In other experiments, milk, urine, beer, mustard-meal, and other substances have been employed, the results invariably proving that fermentation was either prevented or greatly retarded by the addition of salicylic acid. For example, fresh cow's milk mixed with 0·04 per cent. of salicylic acid, curdled thirty-six hours later than a similar quantity of milk to which no agent had been added; urine, to which salicylic acid had been added, remained clear and free from odour till the third day, while another specimen of the same urine, with which nothing had been mixed, was putrid. Its anti-fermentative powers are already so well recognised by chemists in this country, that many of them add small quantities of the acid to such preparations as are liable to undergo fermentative decomposition, with most satisfactory results. These experiments are undoubtedly conclusive as to the value of the agent used as a preventive of fermentation, and experience has proved that it is equally reliable as a preventive and corrective of putrefaction when applied to sores and wounds, and that it materially assists reparative action.

In proof of its powers as a corrector of putrefaction, I may briefly refer to two cases: one of amputation of the thigh, at present under Prof. Pirrie's care in the Aberdeen Royal Infirmary; the other, mammary cancer.

The former patient, a girl aged nineteen, was the subject of extensive necrosis of the femur; she was much reduced, and amputation was had recourse to, but with very grave doubts as to the ultimate result. The vessels were acupressed and water-dressing applied. As was expected, there was considerable suppuration, accompanied by great fetor. The applications used at this time were daily syringing with 1 to 40 solution of carbolic acid and dressings impregnated with red lotion. Salicylic ointment was then applied, and within two days the fetor entirely disappeared and healing action commenced. I on several occasions directed the attention of the students to the almost marvellous change that in this case followed the use of the new antiseptic. Another noteworthy point connected with the case was the extremely small, healthy, and highly vascular condition of the granulations with which the lips of the wound were studded, forming a marked contrast to those which Mr. Callender stated he had seen when salicylic dressings were employed. The ointment used was the one containing paraffin, the formula for which will be found below, and though it is a pretty strong one—1 part of acid to 7,—the patient repeatedly stated that it neither gave rise to pain nor smarting.

In a case of medullary cancer of the mamma, where the fungoid growth involved the entire gland, extended upwards nearly to the clavicle and well down into the axilla, and from which the fetor was so intense that the patient had to be removed to an out-of-the-way apartment, I ordered daily syringing with a 1 to 40 carbolic solution and a liniment of olive oil and salicylic acid, with which the sore was covered. By these applications putrefactive changes were arrested, the fetor disappeared, and the patient was rendered comparatively comfortable, while the attendants were not, as before, repelled from attending to her, which they had been by the disgusting odour pervading the atmosphere surrounding her.

These two cases of themselves show that salicylic acid is a trustworthy antiseptic. But carbolic acid has been proved beyond doubt to be so also, and boracic acid is largely used for similar purposes; therefore, unless salicylic acid possesses advantages over both, its substitution for either cannot be justified. It does, however, seem to me to possess certain advantages, which, though few in number, are not of less importance on that account; they may, I think, be best elicited by comparing carbolic and boracic acids with it. The two manifest objections to the use of carbolic acid, valuable agent though it be, are its irritating action and its smell. Salicylic acid can hardly be termed an irritant, and preparations containing only a small percentage of it can be thoroughly relied on as trustworthy antiputrescents, and it is odourless. These two points constitute its main claims to superiority to carbolic acid. The more important of the two is, however, not yet universally allowed, for, from the statements made by Mr. Callender and Sir William Jenner at the Clinical Society's recent meeting, it would seem that in their experience salicylic acid had displayed most markedly irritant properties. But this is utterly at variance with the observations of continental observers, and also with my own, even where very much stronger preparations have been employed, for, though I have used it constantly since January, in only one case has pain been complained of—in that of a large varicose ulcer of the leg, for which a 1 to 8 ointment was prescribed,—and I have never seen the vesicular eruption, to which Sir William Jenner referred, following its action. But bearing the remarks of these accurate observers in mind, and for the purpose of testing whether it really gives rise to irritation or not, I dusted a granulating surface with the pure acid, purposely selecting a very nervous and susceptible patient, and one who was prone to give vent to his feelings on the slightest provocation. A number of students were present in the ward at the time, and heard the man state distinctly that he felt neither pain nor smarting; an hour afterwards I again visited him, and he still said that there had not been any pain. I then applied a little water to the acid, and rubbed it gently into the surface, but, beyond the slight uneasiness due to the pressure of my finger, he felt nothing, and next day the nurse said that she thought the man had been easier than usual. It seems almost impossible to reconcile this statement with those before referred to as emanating from Mr. Callender and Sir W. Jenner, and so different are they that one would be almost led to infer that either my sample of acid was a very weak one, and theirs a very strong one, or that some impurity had crept into the specimen employed, or that it was due to some peculiarity of constitution of the patients treated by it.

With regard to boracic acid, very many still doubt its reliability as an antiseptic, and I confess I am not yet convinced that implicit trust can be placed in it; but even granting that it is a useful agent, on account of the extreme difficulty of blending it with fatty substances it is the bane of those who have to compound ointments into the composition of which it enters. Salicylic acid can, on the contrary, be easily incorporated with such menstrua; salicylic acid is, on the other hand, only sparingly soluble in water, but a sufficiently strong watery solution can be readily prepared by the addition of a small quantity of biborate of soda and heating. The presence of a minute portion of borax could only seldom be looked on as objectionable, and might in fact be of value in those cases where the action of a mild astringent is indicated. Still, as aqueous solutions of carbolic and boracic acids of the strength now in vogue do not act as irritants, it is unlikely that watery solutions of salicylic acid will ever come into general use, though Thiersch and others employ them. I certainly do not class this as a virtue possessed by the new antiseptic, but for the reasons given it can hardly be looked on as an objection. Finally, salicylic acid is not volatile, therefore dressings impregnated with it retain their antiseptic properties longer; it is tasteless, and non-poisonous.

Preparations of Salicylic Acid.—Thiersch, who follows Lister's mode of treatment, with the exception of the substitution of salicylic for carbolic acid, employs cotton-wadding or jute impregnated with the acid in place of gauze; but as the preparation of his dressings is a complicated process, and requires a lengthy description, I may refer to notices of his paper which appeared in a medical contemporary for May 26th and June 2nd of the present year, where full particulars are given. The watery solutions employed by him contain 1 part of acid in 300 parts of water. As an application to granulating surfaces a lotion containing 1 part of acid, 3 of sodium phosphate, and 50 of water has been found useful. As already mentioned, heat and the addition of borax increase its solubility; a clear lotion of considerable strength can thus be obtained: for instance, ten grains of acid can be readily dissolved in one ounce of water by heating and then adding six grains of borax, or even twenty grains of the acid will be taken up by an ounce of water if fourteen grains of borax are added. These solutions, in addition to their use as lotions, may be used as gargles, where an antiseptic and astringent gargle is indicated. To a surface where it can be accurately applied, and where the discharge is slight, though I have tried it with excellent effect where it was profuse, as in the case of the girl above noticed, the cerate suggested by Professor Lister for rodent ulcer—salicylic taking the place of boracic acid—is a nice application. The formula is from half a drachm to a drachm of salicylic acid, one drachm of white wax, two drachms of paraffin, and two drachms of almond oil; melt and rub up in a heated mortar. It should be spread on strips of muslin or fine linen.

Another ointment may be made of sperm oil, one drachm and a half; oil of theobroma, five drachms and a half; salicylic acid, from half a drachm to a drachm. This forms a thick paste, which should be thickly spread on lint. The heat of the surface acting on the oil of theobroma, a diffusible ointment is formed, which is a suitable application when it is desired to have the discharge thoroughly saturated with the antiseptic. An ointment less easily acted on by the body-heat consists of sperm oil and paraffin, of each a drachm and a half; oil of theobroma, two drachms; oil of almonds, one drachm; salicylic acid, from half a drachm to a drachm.

A very simple and most useful ointment, and one which answers admirably in some affections of the skin, is formed of half a drachm to a drachm of the acid to seven drachms of simple ointment. Though neither watery nor oily preparations of this acid belong to what is termed elegant pharmacy, yet a liniment of salicylic acid and olive oil will be found of much efficacy in burns; as an example, I may cite a case of burn, involving the upper arm and nearly the whole back of a child aged seven, where I recently employed it. Carron oil had been applied; and when my advice was requested, two days after, free suppuration had taken place, accompanied by great fetor. Lint soaked in olive oil and salicylic acid—twelve drachms of the acid to sixteen ounces of oil—was prescribed. The result was most satisfactory; the fetor disappearing, the suppuration rapidly decreasing, the pain greatly abating, and kindly healing action taking place. In less than a fortnight the whole surface was healed, with the exception of two small spots covered by healthy granulations, to which red lotion was applied. I have since found that a much weaker oily solution (two drachms of the acid to eight ounces of oil) was all-sufficient in a case of severe scald of the foot lately under treatment.

For cancerous sores Thiersch recommends dusting with the pure acid, or with equal parts of the powder and starch, or powder formed of charcoal and the acid might be employed for the same purpose, or for dusting over the face of poultices applied to sloughing surfaces. Endless preparations might be devised; but those I have described seem to me as useful as any combinations with which I am acquainted, and therefore I shall leave others to modify them in any way that may suit their tastes or modes of treatment.

Though I stated in the outset that I did not intend entering on details of cases, yet I cannot refrain from urging its use in eczematous affections, for nowhere is its beneficial action more marked than in them. In the eczema of children, more especially in that found affecting the head and face, it is far superior to any remedy I have yet employed; it was, in fact, the results attending the use of salicylic acid in a case of the kind that first convinced me of its value, and I have since found that others have formed a like estimate of it in similar cases. A child, aged eighteen months, had been under my care for many weeks with a patch of eczema rubrum on the cheek; I had tried all kinds of local applications, and had given arsenic and iron wine internally, but with no avail; for though at times it seemed to be giving way to treatment, a fit of itching, I suppose, had caused the child to rub it, and increased irritation always followed. I had not before used salicylic acid, and had but little faith in good accruing from its exhibition, but as a last resource I prescribed an ointment containing one drachm of acid to an ounce of lard. When I next visited the child, a few days after, the patch had nearly healed, and very shortly after it was perfectly whole. In another case the result was almost equally striking, but here it was the first application used. A child, aged six months, had a patch of E. impetiginodes on the occiput; it had first appeared about a month before. As some parts were thickly covered by crusts, a poultice was used to detach them, and then salicylic ointment was rubbed in. In six days every vestige of disease had disappeared. A brother and sister, aged three and five, were the subjects of eczema narium of short standing. Salicylic ointment was applied on a Friday, and on the following Monday the surfaces were perfectly healed. It is unnecessary to occupy space by entering on details of other cases, but I may simply say that in very many I have found it answer admirably.

Aberdeen.

CASES OF SCIATICA AND NEURALGIA SUCCESSFULLY TREATED BY GALVANISM.

BY S. J. KNOTT, M.R.C.S.,
MEDICAL SUPERINTENDENT OF GALVANISM, ST. MARY'S HOSPITAL; LATE TUTOR AND PATHOLOGIST, ETC.

As sciatica and neuralgia are at times most obstinate complaints to treat, even by the most skilful, I have much pleasure in publishing several cases treated by me with galvanism, some of them most chronic, and defying all medicines. If there is any inflammation of the nerve, then galvanism must be used cautiously. I believe in all cases where the nerve is implicated that faradisation would cause great pain, and do harm. The great thing to determine is how the galvanism acts in these cases, because it does good in cases where several counter-irritants have been used, such as blisters, liniments, &c. It depends on the cause of the sciatica or the neuralgia how the galvanism is used, and if the cause is decided on, then the amount of galvanism applied would be, up to a certain amount, as a tonic and stimulant to a nerve which is asthenic; the cells used would be few, and the application light. But if the complaint has been caused by cold, sitting on a wet seat, gout, &c., and the nerve is tender when pressed upon, and the pain very acute, then the cells must be very much increased, and the poles pressed well into the part. The operation should be only for a few minutes, but severe. Sometimes around the cutaneous parts on which the charcoal points have been placed there occurs a herpetic eruption. If galvanism is applied in this way it is the most powerful counter-irritant possible, and the relief to the sufferer is very great.

Sometimes one has to treat cases of neuralgia caused by great debility, at other times shock, and often in two applications the patients are well. Now no medicines do this, and if any apparent benefit is obtained the stomach or some other organ suffers, as the head does in large doses of quinine. Then there is the morphia treatment by hypodermic injection. Now this line of treatment is all very well for the time being, to relieve the great pain and distress, but does it cure the malady? No. About five months ago five cases came under my notice where for months and months men had been treated with morphia injections. One man had got up to four grains and three quarters daily. If this kind of treatment is persisted in where is it to stop? the patient may as well be an opium eater. At last this particular patient got a large abscess in the gluteal region, from the irritation of passing the needle, I presume, and thus got rid of his sciatica. In the case of asthenic neuralgia I believe the mild application of galvanism not only stimulates the weak nerve at the time, but is of a lasting character, for I have often heard a patient say that the whole limb kept warm for two or three days after. I also believe that by this more or less continuous stimulation fresh nerve-cells are caused to be formed, and so the weak nerve is permanently strengthened. And the reason that faradisation is injurious in this class of complaints is that it causes contraction of the enfeebled nerve, and if used strongly a breaking up of nerve-cells, and great pain at the time, and most likely followed by an aggravation of the symptoms. If others have been as successful as myself in the treatment of this class of complaints by galvanism, then I hope it will be tried generally, and it certainly will be a great boon to patients to have this done, instead of taking the powerful medicines some do, and after all only to ameliorate their complaint.

B. G——, aged fifty-four, a surgeon, came under treatment on June 15th, 1873. His history was that two months previous he had got wet and was obliged to sit in his damp clothes for nearly two hours. When he got home he shivered a little and felt cold all over. He went to bed, but was called up in the night and had to go to a midwifery case, at which he stayed some time. On the following day he felt much out of sorts, and in the evening had some pain and stiffness down the back of the left thigh, which, in spite of everything he could do, gradually got worse. He then consulted a well-known physician, and he was put through all the usual modes of treatment, but with little effect; in fact, in spite of very large doses of quinine and aconite liniment, he used to get worse towards night. At the end of the fifth week the pain used to get very severe, and last for about two hours, every twelve hours. He then came to me as a last resource. He walked into my room supported by two sticks. The pain he complained of reached along the left sciatic nerve, commencing just below the sciatic notch and extending to the popliteal space; he also began to feel pain in the loins.

I looked on this case as one of great congestion of the nerve, followed by effusion under the neurilemma; and the pain in the back as caused by the disease extending upwards towards the cord. I advised him to leave off all medicines so as to give the galvanism a fair trial, and to have recourse to the latter daily. I began with eighteen cells of Stöhrer's battery. After the first application he stood up and said, "I believe this will do me good; the whole limb feels warm, which, in spite of wool, flannel, &c., it has not done for weeks." After the first week, I galvanised him only three times a week, then twice; and in three weeks he said he thought he was quite well—at any rate, he would see if he could do without the galvanism; he did so, and has been perfectly well since. He took no medicine from the day he first came, and at the end of the first week left off all the wool and flannel, and only continued his ordinary merino drawers.

E. B——, aged fifty, servant, came into the hospital on February 13th, 1875. She says except an attack of congestion of the liver five years ago, she has always had good health up to nine weeks ago, when she slept in a damp bed. A few days after she was taken with great pain in the lower part of the back and down the left hip, a few days after extending down the back of the thigh and leg to the back of the ankle-joint. The pain always gets worse at night, commencing between 7 and 8 o'clock, and particularly so in wet weather. Ordered hypodermic injection of one-sixth of a grain of morphia twice daily, and ten grains of compound colocynth pill at bedtime. Broth and milk diet.

February 16th.—No better. To go on with morphia injection, and to have a mixture containing three grains of iodide of potassium, ten grains of bicarbonate of potash, and a drachm of glycerine, to an ounce of peppermint-water.

18th.—About the same. Continue injection.

22nd.—A little better. Repeat pill, mixture, and injection.

24th.—Pain worse. Ordered a blister over sciatic nerve.

26th.—No improvement. Mixture twice daily; to be galvanised every other day.

27th.—Twelve cells from Stöhrer's continuous battery applied. Seemed to feel it a good deal.

March 2nd.—Says she certainly has less pain, and gets much better sleep since the galvanism. To leave off morphia injection.

4th.—Is better. Says the galvanism is painful at the time, but thinks it is curing her.

6th.—Is going on well. Mixture to be left off, and only ten cells to be used now. Repeat aperient pill.

9th.—Is much better. To get up to-morrow.

12th.—Pain much less. Is ordered to walk about a little.

16th.—Continues to improve; pain nearly gone. To be galvanised twice a week, and only eight cells used.

19th.—Is now convalescent; only complains of a little stiffness.

22nd.—Discharged cured. She promised to let me know if it returned; but I have heard no more of her.

E. L——, aged thirty-two, came to me on April 15th, 1874. Said he first caught cold; and after that got very weak, and then pain slowly came on in the back of the right thigh. This was about four months ago. Before he came to me he had been an out-patient. He had marks of three good-sized blisters on the back of the thigh and hip, and several small specks could be seen on the hip and thigh. These he told me were the marks of the hypodermic needle; and stated that he had had several kinds of medicine, but they had not done him any good. Of late there was always some pain and tenderness in the back of the thigh, and then at times it would get much worse and the pain would be almost unbearable. He looked very anæmic, his tongue was slightly furred and flabby, his muscles were soft and flaccid, and he said he had lost nearly a stone in weight since he was taken ill.

I galvanised him daily, commencing with sixteen cells, "which he felt very much," and dropping two each day. In eight days he was much better—in fact, so much better that he only had the battery every third day, and only eight cells. In three weeks he was quite well, and went into the country. I have seen him repeatedly since, and he has had no trouble up to the 15th November last, when he caught a severe cold and got wet; and he had, he said, suddenly found the pain return the day before his call. I applied twelve cells three times every other day, and that quite got rid of it. This is the 1st December, and he has had no return.

I believe in the first instance this case was purely of the asthenic form, from the wasting of the limb, the constant wearing pain, and the slowness with which it came on. In the second instance it was different in character; there was great tenderness along the course of the nerve, and the pain was of a more shooting character. This, then, was of the congestive form.

Mrs. L——, aged thirty-eight, came to me April 10th, 1874. She was a thin, delicate person, looked pale and weak, pulse feeble, bowels constipated, appetite bad, nights restless. She said she had had a great deal of trouble and grief during the past month, and ten days before coming to me she was taken with pain in the right side of her face, and down the neck to the clavicle; it was nearly constant, but increased at night, and each day it gained in intensity. The pain seemed very general over the whole side of the face and neck.

I applied six cells of the continuous battery, the charcoal points being covered with lint and dipped in salt and water. I applied them for twenty minutes all over the part affected, and at the end of that time she said, "Thank you; the pain is gone now." She then told me that whenever she was weaker than usual, or worried, she always had neuralgia; and she had tried medicine over and over again, and although it set her right it took days to do so; but whenever she could get the battery applied it cured her at once.

I have no doubt this was a case of asthenia of the nerve, causing pain, and at once relieved by a stimulant tonic, galvanism.

T. D——, aged thirty-one, came under treatment on the 15th Feb., 1875. This was a very chronic case, having, he said, suffered for over two years, without hardly a day's intermission. When first taken with pain in his hip and thigh he had tried a very great many kinds of treatment, and had seen a good many medical men, but for the last twelve months he had done nothing but have morphia injected night and morning, and when the weather was very wet and the pain worse, he had it done three times a day, and had got up to four grains of the acetate of morphia per day! I reduced the morphia to two grains a day, and after ten days left it off altogether, and he never returned to it regularly, but he had to be about a good deal in all weathers, and four times he had a slight relapse for a day or so, and I gave him half a grain at bedtime.

I commenced to treat him with twenty cells of the battery, and pressed it well against the thigh, and after the first week I gradually lessened the strength until I got down to eight cells. He slowly improved, and at the end of two months he was very much better, and went into the country, and that completed his cure. The treatment had not quite fair play, as the man had to go out in all weathers at five o'clock in the morning, and besides this, to keep the cold out, he took a goodish drop of whisky.

I believe in this case there was effusion into the sheath of the nerve, for there was commencing numbness down the leg and foot, and the whole limb was beginning to waste.

J. N——, aged fifty-four, came under treatment April 15th, 1875. He complained of great debility, especially in the right leg, which at times gave way under him, also of pain in the front of the thigh and all around the knee, and at times in the leg. He had heard of electricity he said, and that it would do him good, so he went and got faradised; but it increased the pain he thought, and he only had it done twice.

I commenced with six cells of the continuous current every other day, and this did him so much good I did not increase it. At the end of the second week the pain was nearly gone, and the only thing he complained of was weakness of the limb, but gradually the strength and size came back.

This seemed to me a marked case of asthenia of the nerve. And so the faradisation increased the pain by giving a shock to, and causing contraction with spasm of, the enfeebled nerves, and most likely breaking up some nerve-cells instead of causing the formation of fresh ones as the galvanism does.

Burwood-place, Hyde-park, W.

INTRACRANIAL ANEURISM.

By WILLIAM E. HUMBLE, M.D. Lond.

I am glad to be able so soon to forward, according to promise, an account of the termination—and, I rejoice to say, successful termination—of the case of intracranial aneurism which was published in The Lancet of Oct. 2nd. The fact of its course having been carefully watched from the commencement, and the very interesting and distinct phenomena which attended the consolidation of the aneurism, render the case one deserving of record, and its successful issue affords encouragement for a future trial of a similar mode of treatment.

It will be recollected that the first symptoms of aneurism occurred in March, and the disease, which was at first diagnosed as a case of some kind of tumour at the base of the brain, was recognised to be aneurism at the cavernous sinus about the end of May or beginning of June.

The aneurismal bruit was first heard by the patient on the 17th of March, and by myself, by means of the stethoscope, at the above-mentioned time. The operation of ligature of the carotid having been declined by the patient, and it being found impracticable to carry out fully Mr. Tufnell's method of treatment by absolute rest and restricted diet, I determined on adopting Dr. Balfour's plan of treatment by iodide of potassium. On the 26th of June she began with nine grains of the iodide daily, and the dose was regularly increased till she took thirty-six grains daily. This treatment was steadily continued for just four months, and it is noteworthy that these large doses of the iodide (from Apothecaries' Hall) produced no appreciable symptoms whatever, the patient improving in general health and stoutness.

During the whole of this time the aneurismal bruit continued without intermission, varying in loudness somewhat according to the force of the circulation, and much resembling the sound of a cardiac valvular murmur. About the latter part of September it became louder and rougher for a week, but then subsided to its former intensity. For the last fortnight preceding its cessation I fancied it was not quite so loud, and rather softer than it had been. During the last two months the strabismus diminished, but there was more neuralgia of the brow and side of the head, and she used to complain of the pressure of the stethoscope. The improvement in her general health has been observed by all her friends.

On the morning of October 21st, I was sent for hurriedly at 9.30 A.M. She told me she had had a bad night, the aneurismal bruit having been very loud. She was taken during the night with vomiting and purging, with some headache. The vomiting was attended with much urging, and she was purged, she says, between twenty and thirty times. About 6 A.M. the aneurismal sound became different and constantly varying, at times resembling clanging wires. It then became very feeble, and she heard what resembled several cracks. She then felt very strange, and was astonished at everything appearing unusually silent, when she observed that the sound had ceased. When I saw her no bruit whatever could be heard. She was a little pale and weak, partly from the bad night, and partly because she feared some serious change for the worse had occurred. I explained to her that probably the wished-for event had occurred, and that the first step towards consolidation of the aneurism had been gained. I prescribed some medicine to stop the sickness and diarrhœa, and enjoined the greatest quietude in the recumbent posture, but with the head raised. The right side of the head was very tender, so that she complained very much of the pressure of the stethoscope. This neuralgic condition has existed more or less for some weeks.

Oct. 22nd.—Passed a tolerably good night. No return of the bruit. Says that for about an hour to-day she had slight throbbing within the head. Complains of a strange sensation in the neck and front of the chest, especially if she laughs slightly. No murmur can be heard. Right side of the head still tender, and slight noises, as the opening or shutting of a door, annoy her. Some headache. Says how strange the silence appears to her after seven months and a half of loud pulsation. Iodide to be continued in half the quantity.

24th.—Has suffered more from headache, but not severely. Says she has experienced slight throbbing on the other (left) side of the head. No bruit heard. Pulse continues rather weak, but otherwise normal. Will not remain in bed as advised. The squint has nearly disappeared.

From this time she continued to improve. The throbbing continued for a time in the left side of the head, and was explained to her to be no doubt owing to the artery on that side being enlarged to compensate for the impervious state of the diseased one. She now (Nov. 26th) continues quite well, except some neuralgia. The throbbing has ceased. No bruit has been heard since its cessation on the 21st of October, and I imagine that, five weeks having elapsed, the cure may be considered complete.

Corfe Castle, Dorset.

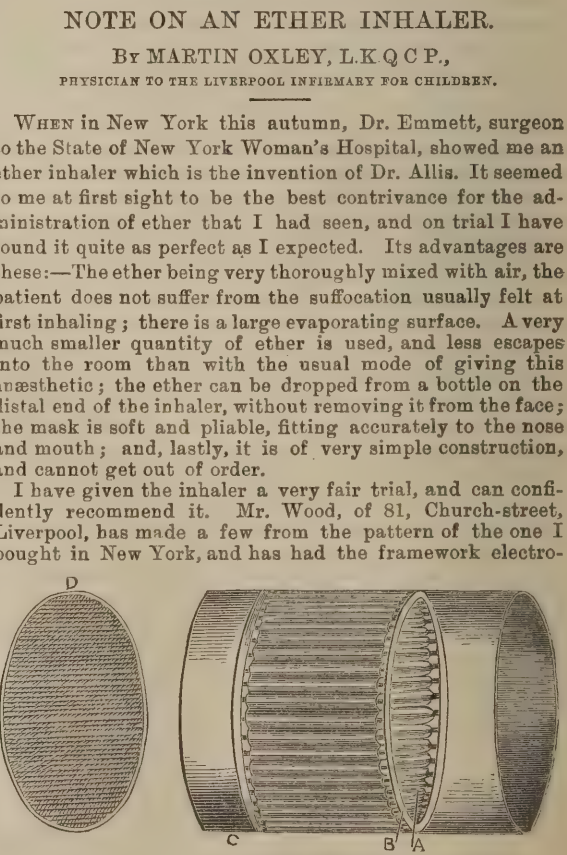
NOTE ON AN ETHER INHALER.

By MARTIN OXLEY, L.K.Q.C.P.,

PHYSICIAN TO THE LIVERPOOL INFIRMARY FOR CHILDREN.

When in New York this autumn, Dr. Emmett, surgeon to the State of New York Woman's Hospital, showed me an ether inhaler which is the invention of Dr. Allis. It seemed to me at first sight to be the best contrivance for the administration of ether that I had seen, and on trial I have found it quite as perfect as I expected. Its advantages are these:—The ether being very thoroughly mixed with air, the patient does not suffer from the suffocation usually felt at first inhaling; there is a large evaporating surface. A very much smaller quantity of ether is used, and less escapes into the room than with the usual mode of giving this anæsthetic; the ether can be dropped from a bottle on the distal end of the inhaler, without removing it from the face; the mask is soft and pliable, fitting accurately to the nose and mouth; and, lastly, it is of very simple construction, and cannot get out of order.

I have given the inhaler a very fair trial, and can confidently recommend it. Mr. Wood, of 81, Church-street, Liverpool, has made a few from the pattern of the one I bought in New York, and has had the framework electroplated. The inhaler consists of two stout oval frames which are joined together by wire bars three inches long and about one-eighth of an inch apart, making a sort of small birdcage open above and below; through these bars a bandage is



A. Bandage. B. Frame. C. India-rubber sheeting.
D. Edge of bandage.

threaded, so as to fill up the inside of the cage, the edges of the bandages presenting at its open ends; over this frame is drawn a piece of stout sheet india-rubber, which has been stitched together at the edges, so as to make a covering for the frame, projecting over one end two inches, to form the mask, and at the other one inch. The ether is poured on the bandage, which forms a close, well-made artificial sponge.

Rodney-street, Liverpool.

A Mirror
OF
HOSPITAL PRACTICE,
BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum, tum proprias collectas habere, et inter se comparare.—Morgagni *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

MIDDLESEX HOSPITAL.

CHRONIC ULCERS OF BOTH LEGS; DRY GANGRENE OF BOTH LEGS—GRADUAL IN RIGHT, SUDDEN IN LEFT.

(Under the care of Mr. Hulke.)

An extremely interesting case of dry gangrene of both legs is at the present time in this hospital. Such a condition as that described below is, we believe, rare, if not altogether unique, in surgical practice. The explanation offered of the mechanism of the gangrene by Mr. Hulke is not only ingenious, but the only one that would account for all the facts. We shall report later on the subsequent progress of this remarkable case. For the notes of its history and progress we are indebted to Mr. G. Sherman Bigg.

The patient, an illuminator, aged thirty-three, had been in the hospital during several of the summer and early autumn months, with chronic ulcers of very old date in both legs. He was discharged on Oct. 12th, greatly benefited by the rest and the care bestowed on him, but with the ulcers incompletely cicatrised. It indeed seemed scarcely probable that they would ever completely and soundly close. After this he stayed at home a fortnight, and then went to his work—illuminating—for two days. On the third morning he noticed that the lower (the unhealed) part of the ulcer in the right leg, just above the inner ankle, was slightly discoloured. It was bluish, then greenish, and next day black. This discolouration shortly extended from the ulcer to the instep, and soon the third and fourth toes became blue, and later black and shrivelled. In this state he applied on the 23rd of November to be readmitted. The two toes, a patch of skin on the instep half the size of the palm of the hand, and the lower half of the ulcer in the right leg were in a condition of dry gangrene. He was placed in Handel ward, and the foot and leg were wrapped in dry cotton-wool, and, as he complained of much pain, he was ordered opium in doses of one grain at intervals, regulated by his suffering. Next day it was ascertained that in the night his left leg had become very painful, and the left foot in the morning was found cold and numbed; it was also dull white and shrunk, and the cutaneous veins, instead of preventing their usual prominence, were indicated by faint, scarcely marked lines, like little channels. It was now discovered that all arterial pulsation was absent below the groins, nor could any be felt in the left external iliac artery. Mr. Hulke was very doubtful whether there was not a feeble pulse in the right external iliac, the uncertainty on this point being caused by the suspicion that the extremely faint pulse which Mr. Hulke thought he detected here might actually be in the deep epigastric artery, and this suspicion was heightened by the very conspicuous collateral distension of the communicating veins of the internal mammary and epigastric systems. This latter feature disappeared after about twenty-four hours.

In the course of some clinical remarks on the 7th inst., Mr. Hulke observed:—This is a case of gangrene beginning and slowly progressive in the right leg, and suddenly supervening in the left leg. The gangrene was dry, and dependent on arterial obstruction. The disease began in the right leg, and the hard cylindroid form of its superficial femoral artery, so far as it was accessible to touch, showed the obstruction to be due to clotting. What, then, was the origin of this? Clots, Mr. Hulke said, originate either at the place where they are found, or they have their origin in a plug or embolon, often a morsel of fibrine, brought by the blood-stream from some distant point. Was the clot in the right leg, so to speak, autochthonic or embolic in its inception? Turning to the heart, there was not any evidence of the existence of valvular disease, so that it was highly improbable that a plug should be derived from this source. Next, by listening to the abdominal aorta, this vessel could be heard to pulsate unusually forcibly for a certain distance short of its bifurcation; at this point the pulsation became very faint, and was now quite inaudible. Dr. Greenhow co-operated in ascertaining these data. The fulness of the patient's belly did not allow of an absolute decision, but the conviction was very strong that the inaudibility of the pulsation here was not due to the presence of any tumour or other extraneous mass overlying the vessel, but to its actual cessation. The origin of the clotting had, then, to be sought in the limb itself. The two chief factors on which the fluidity of the blood depends are, they were aware, the constant motion imparted to it by the heart, and the healthiness—in particular the smoothness—of the vessels through which it circulates. The most common disorder which roughens the inner surface of the arterial tubes is chronic deformitive endarteritis, a process exactly corresponding in the textural alterations it induces to endocarditis. Chronic endarteritis is, however, usually a widely diffused disorder, and as the arteries of the upper extremities and those of the head bore no traces of its presence, both Dr. Greenhow and Mr. Hulke felt compelled to exclude it from consideration. This narrowed down the field of inquiry to the part where the gangrene first showed itself—the lower end of the chronic ulcer. This first, it will be remembered, became bluish-green, then black—in short, gangrenous. He thought it most likely that some of the smallest vessels, bordering on the ulcer, first were obstructed, whether from textural changes induced in them by the proximity of the ulcerative process, or whether some of them gave way and the occluding clot which sealed them passed inwards along their lumen, is of little moment. Once begun, the clot extended peripherally, blocking the arterial twigs supplying the skin of the instep, and later those distributed to the toes, killing those parts and it extended also centripetally, rising through the tibial arteries, through the superficial and common femoral arteries, the external and common iliac arteries, till it projected into the lowest part of the abdominal aorta; there its tapering apex, encountering the downward rush of blood in the main trunk, was swept off by it, plugging suddenly the left iliac or one of its main divisions, when, the obstruction being complete on both sides, the clot grew upwards for a certain height into the aorta itself.

What, Mr. Hulke asked, is the probable forecast in such a case? Though very grave, the man's condition was not hopeless. The gangrene was still slowly spreading, but he judged that it would not ascend above the knees. By using dry dressings desiccation of the mortified parts would be arrested, and by that means the fetor would be kept down and the amount of infective putrid diffusible substances in the limb lessened, and with this the risks of a fatal septicæmia would be diminished. Oakum and charcoal were very useful for this.

In discussing the question of amputation, Mr. Hulke remarked that to do so now, before the eventual limits of the gangrene were known, would be to court gangrene of the stump, necessitating, if the man rallied from the double operation, a second amputation nearer the trunk. Even should a line of demarcation form, the safer plan would be to simply cut through the dead parts, and leave an inch or so of them to be spontaneously thrown off. Such stumps would of course be conical, but later the soft parts could be pushed back and a piece of bone removed if necessary. A not very small experience of gangrene from frostbite gathered in the Crimean campaign, and the unfortunate results of amputation in dry gangrene of limbs in typhoid fever, had taught him that a cautious expectant treatment was safer for the patient than early operative measures in gangrene dependent on arterial obstruction.

Dec. 7th.—His temperature, which since his admittance has varied between 98·8° to 99·6°, has risen to 100·2°. His pulse averages about the same—116. His feet are both becoming darker, although the pulsation is rather stronger, especially on the right side, than previously. He still requires six opium pills a day (one grain each) to keep him free from pain.

9th.—Complains of sore throat, which is somewhat relaxed. Ordered chlorate of potash gargle. The line of demarcation on the right foot is beginning to show itself above.

11th.—The left foot is losing its dark colour and assuming one of a more pinkish hue; the right foot is also improving, but the line of separation above is more marked. His temperature is 101·4°.

13th.—The line of separation daily becomes more conspicuous on the right leg. The two toes, which were black, are still quite firm, and do not show any signs of separating. The left foot is beginning to assume a more natural colour. The pulsation in the right groin is very much stronger, but does not extend below the groin; on the left side the pulsation is not so marked, but is stronger than when the patient was admitted; it also cannot be felt below the groin. Sore throat is now quite relieved. Last night and this morning his temperature has been for the first time normal. Patient states that he feels better and much improved in general health. The thighs are warm.

MOORFIELDS OPHTHALMIC HOSPITAL.

(Cases under the care of Mr. Hutchinson.)

SYPHILITIC KERATITIS AT AN UNUSUALLY EARLY AGE.

Amongst the patients at Moorfields on Monday morning, December 13th, 1875, was a child aged three, who was suffering from well-marked and symmetrical interstitial keratitis of about a month's (?) duration. The child looked healthy, and had a good set of milk teeth, but there was the history that it had been treated at St. Bartholomew's Hospital in infancy for a long-continued rash and severe snuffles, and that it was then not expected to live. Mr. Hutchinson remarked that the interest of the case was in the unusually early age at which the keratitis occurred. There could, he said, be no doubt, from its character, that it was due to inherited syphilis, but he did not recollect ever to have identified this form of eye disease in so young a patient; he had several times seen it at five years old, but as a rule it did not occur till from eight to ten, and was yet more frequent about the time of puberty; it might even be delayed to the age of thirty or thirty-five, and then develop in a most characteristic manner. He was not prepared at present to give any explanation of this wide difference of range.

SUPPURATION OF THE LACHRYMAL SACS IN INFANTS.

A child of three years old was brought on account of discharge of matter from the eyes. The mother stated that her doctor discovered within a few days of the child's birth that matter came from the corners of its eyes, and that this had persisted ever since. There had never been any inflammation of any part. On pressure over the lachrymal sac pus regurgitated freely through the canaliculi. Mr. Hutchinson remarked that he had seen but one similar case; in that instance he was consulted by a surgeon in the case of his own child, an infant of a few days old, which had suppuration of both lachrymal sacs. There was no redness or evidence of inflammation. Pressure over the sac caused a free escape of puro-mucus. On account of the delicacy of the parts it was thought better, for a time at least, to abstain from mechanical treatment; and in the course of a few weeks, under the use of an astringent lotion, it entirely ceased. It was very difficult to form any conjecture as to the cause of the symptom in these two cases. Both the children were quite healthy; in both it occurred so immediately after birth that it was difficult to suspect any exposure to cold, and in both it occurred on each side, making the action of any accidental cause improbable.

STANLEY HOSPITAL, LIVERPOOL.

SUCCESSFUL CASE OF HERNIOTOMY; REDUCTION OF LARGE MASSES OF OMENTUM.

(Under the care of Mr. Rushton Parker.)

Old omental hernia; strangulation of ileum; sac congenital.—A labourer, aged fifty-two, had had for two years a reducible left inguinal hernia, which he kept up easily with a truss. For about thirty years he had had an irreducible right inguinal hernia, for which he had never worn a truss, and which increased in size at times, the increase having always disappeared when he lay down.

On the 1st April, 1875, this additional portion came down soon after mid-day, when he had eaten an unusually hearty dinner, and he could not reduce it. For two days he remained at home, unable to work, or eat, or rest, and he came to the hospital on 3rd April among the out-patients.

On admission he had a large three-lobed tumour of the right scrotum, the smallest lobe being in front and having the size and shape of a testicle, but feeling as if it contained fluid. No translucency, however, could be detected in any part of the swelling, which also was everywhere dull on percussion. There was pain in the abdomen, which was tense, but not enlarged, and he appeared thoroughly uncomfortable and rather restless, though not anxious or seriously distressed. The pulse was not perceptibly abnormal, and there was an entire absence of vomiting. An occasional eructation, however, gave a clear warning of impending strangulation of an obstructed hernia.

He was put to bed with the pelvis raised and knees flexed, and had a quarter of a grain of morphia subcutaneously every four hours, after a reasonable trial of taxis, which failed. Three or four hours later he vomited a glass of brandy-and-water which had been given him, and twelve hours after admission regular stercoraceous vomiting set in and lasted at moderate intervals for six hours more, when he was put under chloroform.

The operation was performed fifteen hours after the first act of vomiting, six hours after the first appearance of stercoraceous matter, and exactly three days after the descent of the hernia. A vertical incision was made down to the external oblique muscle, and an attempt made to reduce the hernia without opening the sac, by first incising the edge of the external ring, but this failed. The sac was opened, and a piece of small intestine was found extending down into mid-scrotum. A narrow neck was found at least two inches below the external ring, much less than half an inch wide. This was incised, and a couple of inches of gut, slightly reddened but uninjured, was liberated, and returned with the portion above into the abdomen, constantly irrigated, after exposure, with 1 per cent. carbolic lotion (the spray apparatus not being at hand). About three-quarters of a pound of omentum was next pulled from the scrotum, passing through the narrow neck by a still narrower pedicle, and being found quite healthy was returned into the abdomen, after being well washed with the carbolic lotion. Much fluid escaped with the release of the omentum, which was found to occupy a congenital sac, the small diverticulum of which was stripped up and cut off.

The inguinal neck of the sac was sown up with carbolised catgut, and carbolised waxed silk sutures were used for the external wound.

The abdominal part of the wound healed without suppuration, but pus formed in the scrotum by the fourth or fifth day. The man was up wearing a double truss in five weeks. In spite of the continual administration of morphia or opium, he had stools each day after the operation for several days, but, fortunately, without harm. He vomited twice after the operation on the same day; and on the fourth day was much distressed by hiccough for many hours, but this disappeared at once on his following an old popular plan of slowly sipping some liquid (milk in this case) as long as he could without breathing.

Bequests, &c., to Medical Charities.—Mr. Frederick Sheppard bequeathed £1000 to the Seaside Convalescent Hospital, Seaford, and £300 to the Chelsea Hospital for Women. Mrs. Johnson bequeathed £500 to the Chesham Hospital.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE ordinary meeting of this Society was held on the 14th inst., Sir James Paget, F.R.S., President, occupying the chair. There was a very large attendance, and the whole evening was occupied by the question of the operation of abdominal section for the relief of intussusception, which was raised in three communications by Mr. Howard Marsh, Dr. Fagge and Mr. Howse, and Mr. Hutchinson. In the discussion that followed it was evident that there was a prevalent opinion as to the advisability of the operation in cases where other means of reduction failed; and, although it was somewhat lost sight of in the debate, it must not be forgotten that it is to Mr. Hutchinson that is owing the introduction of this new method of successfully treating cases which, if left alone, would inevitably terminate fatally. Sir James Paget but expressed the whole feeling of the meeting when he said that this operation was destined to become as prevalent and as valuable as ovariotomy.

The first paper read was that contributed by Mr. HOWARD MARSH on a "Case in which Abdominal Section was successfully performed for Intussusception in an Infant seven months old." The child, a patient of Dr. Miller and Dr. Barnes, of Eye, in Suffolk, was attacked on the 29th of last March with symptoms apparently of dysenteric diarrhœa—sickness, griping abdominal pains, and too frequent action of the bowels. This condition was for a time relieved by medicine, but in two or three days it recurred, and was then accompanied with tenesmus and the passage of blood and slimy mucus. The child remained about the same, but with no serious disturbance of the general health, till the morning of April 11th, when the whole complexion of the attack suddenly changed: the pain became very severe, sickness frequent, tenesmus violent and almost constant, and he grew pale and restless. Dr. Barnes found the bowel projecting two inches beyond the anus, and could see the ileo-cæcal valve at the extremity of the protrusion, while in the abdomen a firm cylindrical tumour was felt extending in the course of the descending colon from the left of the umbilicus to the left iliac fossa. Insufflation and the careful distension of the large intestine with lukewarm water failed to reduce the intussusception. When the child was seen late in the evening he was in a state of collapse, with a frequent and feeble pulse; he was, moreover, pale, and frequently sick. It was then decided to perform abdominal section. Accordingly, chloroform having been administered, Mr. Marsh proceeded to open the abdomen to the extent of two inches in the middle line, just below the umbilicus. Great care was required to avoid wounding the intestine, which protruded into the wound. Failing to reduce the intussusception by the introduction of two fingers into the abdomen, the bowel was first withdrawn from the abdominal cavity; reduction was then easily effected. It was difficult to estimate the precise amount of bowel invaginated, but it comprised at least one-half of the colon and an equal part of the small intestine. The only difficulty in the operation consisted in the return of the considerable amount of intestine that now lay on the surface of the abdomen, but this was accomplished without any great delay, and the wound was closed with harelip pins and superficial sutures, being further supported by strapping and a bandage. Small doses of laudanum were given, and milk and water with occasional addition of brandy. No bad symptoms followed. Sickness ceased at once after the operation; flatus was passed on the next, and a feculent motion on the third day; the sutures were removed at the end of eighty-four hours, and the child was convalescent on the fourth day. Mr. Marsh remarked that the interest of the case was increased if it be read in connexion with Mr. Hutchinson's paper on the same subject, published in the 57th volume of the Medico-Chirurgical Transactions, for it confirms in a striking manner that writer's observation that in many cases of intussusception the volvulus is neither inflamed, adherent, nor strangulated, but is like a piece of intestine lying loose in a hernial sac, and admitting of being easily reduced by an appropriate slight force. In the present case it seems almost certain that the intestine was for thirteen days merely invaginated, and that inflammation, with all its attendant dangers, set in only twelve or fourteen hours before the operation. Mr. Hutchinson in his paper expressed his anticipation that abdominal section would be less likely to succeed in very young children. This, however, to judge from the present instance, is not the case. Mr. Marsh concluded by referring to the necessity for the careful consideration of any particular case before the operation is performed; but he thought it should be undertaken, if all other means had failed—(1) in acute cases of not more than twelve or eighteen hours' duration; and (2) in chronic cases, in which there had been no symptoms of inflammation or strangulation of the intestine.

The second paper was contributed by Dr. HILTON FAGGE and Mr. H. G. HOWSE. It dealt with a "Case of Intussusception in an Adult, without symptoms of Strangulation, treated successfully by Abdominal Section." The case recorded in the paper was that of a woman, aged thirty-three, whom Dr. Fagge was called to see in consultation with Dr. Adcock, of Abbey-street, on June 28th, 1874. She had been suffering for fifteen days from paroxysmal pain in the abdomen, and after she had complained of this for eight days, Dr. Adcock had observed a tumour which was at first situated in the right iliac fossa, but which afterwards moved over to the left iliac fossa. She had had a little sickness, but no decided constipation. The tongue was clean, the pulse was scarcely above the natural rate. From the character of the tumour it was diagnosed as an intussusception, and inflation of the rectum was practised the same day, but with no result. On June 29th Mr. Howse was called in, and the bowel was again inflated with better instruments. This gave intense pain, but had the effect of altering the position of the tumour, which now lay behind the umbilicus. On June 30th inflation was practised for the third time, without producing any change in the tumour. On July 1st the condition of the patient was the same. She had had a slight return of the sickness in the morning, and a little pain; her bowels had not been open since the first inflation; the tumour was still to be felt. Another consultation was held, and, having obtained the consent of the patient and her husband, Mr. Howse proceeded to open the abdomen by a vertical incision opposite the umbilicus. The intussuscepted mass was readily felt, and as it could not be reduced *in situ*, it was drawn out of the wound. Even then pulling at the ends failed, and it was only by a kind of kneading movement, with pressure upon the distal end, that reduction was effected; and it was particularly noticed that there was a little hitch just when the last part of the invaginated mass was emerging. The length of the included bowel was at least eighteen inches. All the precautions of the antiseptic method were employed during the operation and in the after-treatment, and special care was taken to prevent any considerable quantity of carbolic lotion from flowing into the peritoneal cavity. She recovered without a bad symptom, the temperature never rising above normal, and the wound healing by the first intention. At the present time she is well, and expecting her confinement. In this case hæmorrhage from the bowels was absent, which has hitherto been regarded as a cardinal symptom of intussusception. In their remarks the authors showed that it was of great importance not to delay the operation of abdominal section until hæmorrhage occurred. The significance of this symptom had hitherto been misunderstood. It had been supposed by some writers, including Dr. Fagge, to indicate the commencement of the processes which lead to the sloughing and detachment of the invaginated part of the bowel. The authors now pointed out that this is a mistake, but they also showed that it often is evidence of extreme congestion and swelling of this part—a condition which may destroy the patient's life in a few days, and which may render the operation of abdominal section a failure by making it impossible to reduce the intussusception when the abdominal cavity has been opened.

The third paper was by Mr. JONATHAN HUTCHINSON. It was entitled "A Second Case of Abdominal Section for Intussusception into the Colon; with Remarks on the Details of the Operation." It consisted of the narration of a fatal case of operation for intussusception in an infant, aged six months, whom he had attended in consultation with Dr. Madge. The intussusception involved the whole length of the colon, and the ileo-cæcal valve, introverted, constituted its extremity, and was easily felt by the finger in the anus. The symptoms had been the usual ones; they had lasted three days, and the usual method of treatment, perseveringly carried out, had failed. As the child was evidently about to sink, the operation was at once performed. Considerable difficulties were encountered in effecting the reduction of the intussuscepted part. Its neck was tied back in the loin by the meso-colon, and could not be brought into view, and, although there were no adhesions, it was found quite impracticable to draw the intussuscepted bowel out of the sheath. At length it was discovereed that although the upper end of the intussusception was fixed, its lower one, containing the sigmoid flexure of the colon, was quite loose. This was readily brought out, and by gently pulling the sheath downwards reduction was without difficulty effected. The appearance of the appendix vermiformis, just at the completion of the reduction, confirmed the opinion formed as to the introversion having begun at the cæcum. Considerable difficulty was encountered in replacing the intestines within the abdomen. They were accordingly punctured with a harelip needle in two or three places, and at the conclusion of the operation the infant was in an alarming collapse. It rallied, however, afterwards, took the breast, and passed a motion. Death occurred about six hours after the operation, and the post-mortem showed evidences of recent extensive peritonitis. In connexion with the fact that the child's sister had died at the same age a year ago with a precisely similar condition of things, it was of interest to note that the cæcum appeared to be quite loose, possessing a mesentery, which allowed of its very free displacement. The author suggested that this condition as a congenital peculiarity is probably the one which admits of displacement of this special part. He stated also that one of his chief objects in bringing the case before the Society was to suggest, for the guidance of future operations, the propriety of always seeking first the lower end of the intussusception. He believed it would generally be found much easier to bring the lower end into the wound without allowing escape of the rest of the intestines. He thought it probable also that it would usually be found much easier (as it was in this instance) to effect reduction by drawing the sheath downwards from off its contents, than by drawing the contents upwards from within the sheath. The difficulty in reducing by traction results from the fact that the sheath becomes puckered up into rings, which act as so many strictures upon its contents. He thought it even possible that, by attention to this rule, reduction might sometimes be effected without bringing the parts externally.

Dr. BUZZARD opened the discussion. He said that he would keep strictly to the point as to the advisability of the operation. Dr. Brinton had pointed out that out of 600 cases of intestinal obstruction, forty-three per cent. were due to intussusception; and of the cases of intussusception thirty to forty per cent. terminated favourably. Thus Brinton, in considering the question of gastrotomy, found himself compelled to eliminate intussusception, the operation being only of value in the early stages of the affection, when the condition was not one of obstruction, but of enteritis. Dr. Buzzard said that he would be inclined to place the proportion of reducible intussusception quite as high as Brinton did, and he inquired whether a dangerous operation was justified in a disease of which the proportion of cases capable of relief by other means is so high?—Mr. MAUNDER related two cases of intussusception in infants, one in which reduction was effected by inflation and injection of water; and the other where, although the ileo-cæcal valve presented at the anus, there was spontaneous reduction. He characterised the papers of the evening as indicative of new triumphs in modern surgery, and drew attention to the points insisted on by the authors.—Dr. WEST thought a distinction should be drawn between intussusception in the adult and in the child. In the latter the diagnosis is not difficult, and one of the earliest signs is the passage of blood or blood-stained mucus. It had seemed to him that this depended on the position of the intussusception, and took place from the constricted and congested bowel. The diagnosis was not difficult, even in cases where the invaginated intestine could not be felt, and where there was only indistinct fulness of the abdomen. A certain proportion of these cases—not so many as Dr. Brinton had stated—recovered independently of treatment, or under simply soothing applications. Others, again, only yielded under inflation or injection; experiments, however, which should not be pushed beyond reasonable limits, remembering the susceptibility of the nervous system in childhood. It was a question, indeed, how far the nervous system of the child could bear the shock of an operation. Dr. West concluded by saying that when every other means had failed in producing reduction, surgery must be had recourse to, and the cases related gave every hope of success. The changed light in which abdominal surgery was now regarded was interesting to one who contrasted the present views with those held twenty-five years ago, and we had learnt from ovariotomy that long incisions into the peritoneal cavity might be made with impunity.—Dr. E. G. BARNES, in whose practice occurred the case related by Mr. Marsh, said that the child was now perfectly well, and the cicatrix in the abdominal wall was quite firm. It was important to note the difference between intussusception in the child and in the adult; and between those cases where the invagination took place at the ileo-cæcal valve, and those of the small intestine, which occurred after sloughing. The diagnosis of intussusception was not more uncertain than that of any other internal disease—e.g., pneumonia or pleurisy. That length of time during which the intussusception had lasted was not, as supposed, sufficient to render the case a hopeless one, from the fear that adhesions might have been set up, was, he thought, shown by Mr. Marsh's case. In two cases which he had examined after death—one in which the invagination had lasted three days,—it was comparatively easy to reduce the intussusception. Granting, then, that the diagnosis is certain and the case not hopeless, it is imperative to have recourse to operative interference if other means have failed in effecting reduction. Injections, together with insufflation, should always be tried.—Mr. T. SMITH drew attention to the significance of hæmorrhage, which could not occur if there were complete strangulation. He did not think the size of the incision of much moment, since, if we have learnt anything from ovariotomy, it is that mechanical interference with the peritoneum is not an element of great danger. The danger in such cases lay in the retention of a little blood or pus in the peritoneal cavity, and all the viscera could be sponged with impunity. The length of the incision would probably facilitate the operation, the only difficulty thus produced being in the return of the bowel. It would be often necessary to puncture the intestine with a fine trocar or needle. In reply to Dr. Buzzard, Mr. Smith said that surgical interference would not be had recourse to unless other means had failed. He did not think any value could be placed on Dr. Brinton's statistics, and he believed that were Dr. Brinton now living, he would have found reason to alter his opinion on this head.—Mr. HOLMES thought that a long incision would facilitate the return of the bowel. He had only once performed abdominal section (for intestinal obstruction), and although the incision was a free one, he had no difficulty in returning the gut into the cavity. He agreed with Mr. Smith as to the inutility of making any deductions from alleged cases of recovery. It should be remembered that those cases in which an operation was deemed necessary were mostly cases which, if left alone, would probably not recover. With regard to hæmorrhage, he thought the occurrence of blood in a hernial sac was evidence that bleeding could take place from strangulated intestine. The three cases under review were different: in Mr. Marsh's and Mr. Hutchinson's cases it was evident that unless relieved their condition was hopeless, but it was impossible to say if this were so in Dr. Fagge's case.—Mr. GEORGE POLLOCK thought the hints contained in the paper by Dr. Fagge and Mr. Howse, as to the danger of over-distension by injection, were of great importance. Some years ago he had made some experiments on this point, and found that when the bowel was but slightly distended the peritoneum was very apt to crack. This rupture of the peritoneal coat might be the cause of peritonitis.—Dr. HARE pointed out that the cases could be grouped under two categories—one in which the bowel was constricted, the other in which it was strangulated. In the former class there was great congestion of the intussuscepted portion, for the reflux of blood by the veins was cut off, but the arteries still remained patent. He urged the injection of *ice-cold* water to reduce this congested state. He had in analogous cases succeeded by this means, aided by application of ice to the abdomen. Not only did cold act by emptying the congested vessels, but also by diminishing the volume of air in the bowel. — The PRESIDENT, in calling upon the authors to reply, said that the papers were of great value, opening up a large field of abdominal operation, which he believed would be as fruitful in result as ovariotomy was. He could remember when the value and expediency of ovariotomy had been called in question at this Society.—Mr. MARSH said that the question really was, what degree of risk is incurred in the operation of abdominal section *per se?* Was it more than in any other capital operation? Certainly the history of ovariotomy had shown with how great impunity the abdomen might be laid open, and the power of resistance to such ordeal was exhibited in cases where the operation had been accompanied by pregnancy. The favourable results of ovariotomy, as contrasted with those obtained in the earlier days of the operation, were largely owing to the increased care taken to remove all septic fluids from the peritoneum. He concluded then that abdominal section was not a dangerous operation. As to the selection of cases of intussusception, he thought acute cases of twelve or eighteen hours' duration might be operated on, and he related a fatal case of obstruction, due to internal strangulation, with symptoms of eight days' duration, and the patient did not come into hospital until the time for successful operation had passed. — Dr. HILTON FAGGE said that the point which he and Mr. Howse had wanted to show in their paper was that the occurrence of hæmorrhage indicated a change in the bowel—an increasing congestion,—and therefore the greater danger of deferring operation. If that condition could be anticipated, the bowel could be more easily reduced at the time of operation. In the present case Dr. Fagge stated that in determining on the operation he was no doubt influenced by a case which he had seen in which no hæmorrhage occurred, and no operation was undertaken; that case terminated fatally. With regard to statistical facts, he said that no one more carefully collected his cases than Dr. Brinton, but it must be remembered that a large number of cases of intussusception were not diagnosed until the invaginated segment sloughed and was passed per anum.—Mr. HOWSE referred to the advisability of puncturing the intestine, which, owing to the great difficulty experienced in returning the bowel, was often found to be necessary. In two cases he had punctured the intestine with a fine trocar and canula, but had found that, owing probably to the inflamed state of the bowel, and consequent paralysis of the muscular coat, the punctures did not close, and a gradual oozing of fæces took place, leading to fatal peritonitis. This seemed to have occurred in Mr. Hutchinson's case. In one case he had tried to sew up the small aperture, but found this very difficult from the softened condition of the serous coat. He thought in such cases it might even be wiser to make a free incision into the intestine, and then sew the margins of the wound together. The hæmorrhage in intussusception probably took place in the first stage of strangulation, before that was complete; and he did not think the analogy of bleeding into a hernial sac held good as evidence that hæmorrhage took place from a strangulated bowel; for it must be remembered that in hernia the sac itself might be the source of the hæmorrhage, especially as most blood was found in cases where taxis had been much applied.—Mr. HUTCHINSON said that much light would be gained if statistics were compiled of cases of intussusception of the colon where the cæcum appeared at the anus, and the characteristic sausage-like mass could be felt in the iliac fossa. Before his first case all such cases he had seen had ended fatally. With regard to the operation, he was not inclined to regard the length of the incision as unimportant. There was no analogy with ovariotomy, where one had to deal with flaccid abdominal walls after the removal of a large tumour. In intussusception, on the other hand, all the contents of the abdomen that were extruded had to be replaced, and this replacement was difficult just in proportion to the length of the incision and the amount of prolapsed bowel. He had sometimes to reduce the size of an incision before he could replace the intestines. The present was the only case in which he had punctured the intestine, and he hoped never to do it again. It was to this puncture that he attributed the fatal issue.

The meeting then adjourned.

CLINICAL SOCIETY OF LONDON.

THE ordinary meeting of the Society was held on Dec. 10th, Dr. Buzzard in the chair. Some very remarkable cases of cures of diabetes by skim-milk were brought forward by Dr. Donkin, and Mr. Haward narrated a case of bold and somewhat novel treatment of lymphadenoma, which elicited an interesting discussion. There was a very fair attendance of members of the Society, although not so good as usual. The election of Sir Thomas Watson, Bart., and Dr. C. J. B. Williams, as honorary members of the Society, was announced.

Dr. SCOTT DONKIN brought forward a case of Diabetes cured by the use of skim-milk. The patient, who was shown to the Society, was a hale, robust-looking man, forty-five years of age, a carman by trade. He had an accident three years ago, suffering a blow on the head, which laid him up for a while. At the end of June, 1875, he had another accident: his cart coming into collision with a cab, he fell between the shafts, and was dragged some distance and bruised, but not severely injured. Soon afterwards he began to suffer from polyuria, with great debility and much thirst, but the practitioner whom he consulted did not recognise the case as one of diabetes, and sent him into the country for change of air. There, on an unrestricted diet, he grew rapidly worse, and, as the existence of diabetes was suspected, he was sent back to London. On Oct. 6th he was first seen by Dr. Donkin, having then suffered from these symptoms for six weeks. At that time he was passing daily from twelve to fourteen pints of urine, of sp. gr. 1045, containing a quantity of sugar, which was estimated, by means of Duboscq's polarising saccharometer, at twenty-eight grains to the ounce. There was urgent thirst, a parched mouth, dry skin, and great voracity, and the sight was impaired. There was loss of sleep from the frequent calls to micturate at night, great debility, and loss of flesh, but no other complications. The patient was at once (on Oct. 7th) put on skim-milk diet, seven pints a day, without other food. Two days later the quantity of milk was increased to eight pints a day. The treatment was followed by a rapid diminution in the quantity of urine, and on the fifth day from its commencement only four pints and a half of urine were passed. On Oct. 14th, or seven days from the commencement, the specific gravity of the urine was 1010, and there was no sugar to be discovered in it. The health had greatly improved, the patient slept well, having no calls to pass urine at night. Nine pints of milk were now allowed per diem, a part being given as curd. On Nov. 5th three-quarters of a pound of mutton chop was added to the diet, the skim-milk being reduced to six pints. On the 12th the specific gravity of the urine was 1012, and he was allowed an additional chop. On Nov. 18th, or six weeks from the commencement of the treatment, the patient's health was restored and there was no sugar in the urine, and he was allowed some fish. On the 21st he resumed his occupation, which he has since continued. On Dec. 3rd he was seen again; he came then free from disease. On the 10th his urine was of sp. gr. 1017; no sugar could be discovered with Fehling's solution, and the quantity was from four pints to four pints and a half per diem. He was now allowed some tea and a little pale brandy. In remarking on the case, Dr. Donkin observed that some might be inclined to regard it as one of traumatic origin, but this was not his opinion. The great quantity of sugar passed and the rapid emaciation showed the case to be a very severe one. It was a fact of great importance that the copious formation of sugar was arrested under a diet which contained eight ounces of milk sugar per diem, that being the estimated quantity in the amount of milk taken, and it corroborated the observation which he had previously made, that lactose does not cause an increase in diabetic sugar. Dr. Donkin also gave some particulars of another case under his care—a young lady ten years of age, who for three months had been suffering from great thirst and frequent micturition. The practitioner who was consulted found the case to be one of diabetes. The specific gravity of the urine was 1040, and it contained much sugar. He ordered a meat diet and small quantities of Dover's powder. She still, however, suffered from thirst and occasional giddiness, and on Oct. 2nd she was put on a diet of skim-milk, which she continued for ten days. This was followed by a rapid fall in the specific gravity of the urine, which reached 1010 on October 12th, when she came to London to consult Dr. Donkin. The same treatment was continued, and on November 6th she was seen by Sir T. Watson, who stated that the specific gravity of the urine was 1015, and it contained neither sugar nor albumen. Since that time the patient had continued well, and on December 6th the specific gravity of the urine, which had varied from 1014 to 1016, was 1023 (the quantity of urine being less than usual); the child was in good health and spirits, and the diet was being gradually altered towards an ordinary one. Dr. Donkin remarked that these cases show in a striking way the arrest of the disease by the treatment when it is applied in the early stages, before the disease has been fully established or has produced irremediable lesions. The fact that the method was so often applied only as a last resource, when all other measures have failed, must be borne in mind in estimating the value of the treatment; this was especially the case with hospital patients, who so often only apply for relief when broken down and worn out by the disease, and hence the frequent failure to obtain any successful result.—Dr. Coupland inquired whether the patient was of temperate habits, or was in the habit of taking malt liquors.—Dr. Donkin replied that he was very temperate and moderate.—Dr. Glover suggested that the urine should be examined by the secretaries in order that confirmation might be given to the remarkable facts of the case. One very striking fact in the history of the case was that the patient had actually, as he had ascertained by questioning him, lived solely on skim milk for a month. Moreover, he was restored to perfect health. Now if any other remedy were introduced which produced half so remarkable effects, we should think it a very important addition to the pharmacopœia. The second case was even more astonishing, as the disease in old people may often be held in check for a long time by careful dieting, but in early life they were usually much less amenable to treatment.—At the suggestion of the chairman, Dr. Glover and Dr. Southey made an examination of the urine, and reported that it was entirely free from sugar.

Mr. Warrington Haward read the notes of a case of Lymphadenoma. The patient was a little girl, four years of age, who came under his care at the Children's Hospital. When first seen, there was a mass of enlarged glands on the left side of the neck, occupying the anterior and posterior triangles, and nearly reaching the middle line; it measured four and a half inches vertically and six inches transversely, and was most prominent at the upper part. The mass was firm, freely movable beneath the skin; the superficial veins prominent; the skin natural. There were no enlarged glands elsewhere; the liver and spleen were not enlarged; and there was no increase in the white corpuscles of the blood. The temperature was normal. The child's parents were healthy, but two relatives had died of phthisis. The child had had measles and small-pox, the latter a year previously; and soon after a gland behind the left ear began to enlarge; this was followed by others lower down in the neck. Then loss of flesh began, but no other glands enlarged till shortly before admission to the hospital, when she was pale and thin, but intelligent and cheerful. Mr. Haward determined to remove the gland in order to avoid, if possible, any further infection of the system. This was done on July 10th; the anterior triangle of the neck was exposed, and the enlarged glands shelled out, the carotid sheath being exposed during the operation. The wound was dressed with antiseptics. On the following day the temperature was 101°; pulse 100. The patient had slept well. There was a rapid subsidence of the traumatic fever, and on July 29th the wound was almost closed. On the 30th the glands were removed in a similar manner from the posterior triangle of the neck, the wound being treated as before. The febrile reaction was much greater than before, but the wound did well, and by the end of August was nearly cured, and the child left on August 30th much improved in every way. On October 9th she was again admitted with slightly enlarged glands at the angle of the jaw, and on November 5th there were growths in the axilla and some also in the mediastinum. There was rapid emaciation and great pallor, and the temperature rose to 102° every evening. The glands rapidly increased in size, masses appearing on each side of the neck, in the axilla, and in the right groin. There was great emaciation, no diarrhœa, but slight cough, and the evening temperature was about 103°, that in the morning about 98°. She gradually became weaker, and died on Nov. 14th. At the post-mortem masses of enlarged glands were found in the neck, the axilla, groins, and anterior mediastinum; the lungs contained numerous grey semi-transparent granulations; the liver, spleen, and peritoneum also contained numerous small nodules of adenoid growth. Mr. Haward said that when Hodgkin first described the disease, he stated that there was no treatment of any value, and this was still the case after the lapse of forty years. It seemed to him, therefore, that when the earlier growths were in a readily accessible situation, we might, by early removal, prevent the occurrence of general infection. Cases were sometimes fatal even before this occurred, as in a case to which he referred, where death was caused by pressure on the œsophagus. In this child the disease was confined to one side of the neck for a year, and a remarkable alteration ensued on the operation. No return had occurred in the posterior triangle—a fact which Mr. Haward attributed to the more complete removal possible. At any rate, it was justifiable to attempt operation in so serious a disease, if there were any chance of arresting it.—Dr. Douglas Powell remarked that his own feeling with regard to this novel method of treatment was one of doubt, and he should differ from Mr. Haward with respect to the prospect of its being of any use. He was strongly of opinion that the glandular enlargements were of constitutional origin, and that the situation of the enlargement was more the result of accident than of anything else. Probably the explanation of the frequency of scrofulous enlargement of the glands in the neck was to be found in the frequent irritations about the head in children, but these only acted as determining causes. And he should fear that such an operation as that described would tend to set up further irritation in other glands.—Dr. Southey inquired whether any nervous symptoms had been observed during life, to which Mr. Haward replied in the negative.—Mr. T. Norton said that he had removed similar masses from the neck, but he was inclined to believe them to be of constitutional origin, and they might be reduced by treatment. He would not operate if the enlarged glands passed more deeply.—Dr. Silver observed that Mr. Norton was speaking of a disease of an entirely different nature. He wished to mention the case of a woman who had recently been under his care, who had a mass of enlarged glands in the left side of the neck, over which the skin was freely movable. There was also evidence of masses in the mediastinum and of enlargement of the spleen. In that case there were certain clinical features of interest, one of the most characteristic of which was a great variation of temperature. Another point was that the red blood-corpuscles were not numerous, and they exhibited a tendency to run together into masses, and not into rouleaux; the blood also contained masses of granules, apparently of a fatty nature.—Dr. Greenfield had also observed in two cases a very remarkable condition of the temperature, which rose very rapidly to 105·5° or 106°, falling again with equal rapidity. These attacks of rise of temperature were sometimes attended with slight shivering, and sometimes with slight discoloration of the skin. They were so transient that they would probably not be observed if the temperature were taken only in the morning and evening. He inquired whether Mr. Haward had observed clusters of small red spheroidal corpuscles in the blood, such as had been described by the name of microcythæmia, which he had found in the blood in one such case. He was inclined to believe, with Mr. Haward, that the disease was an essentially malignant one, and that although histologically the growth in the glands, and in the liver, spleen, &c., might be indistinguishable from that occurring in other forms of overgrowth or new formation of adenoid tissue, yet that in its life history and mode of growth and invasion it exhibited a distinctly malignant type. He adverted also to the inconvenience and confusion which resulted from grouping together and applying the names of lymphoma, lymphadenoma, &c., to diseases so different as simple overgrowth of the glands, new formation of adenoid tissue of non-malignant type, whether homologous or heterologous, and the essentially malignant type, simply on account of their similarity in microscopic structure.—Dr. Powell inquired whether Mr. Haward had been able to make the diagnosis of Hodgkin's disease in this case, and if so on what grounds, as there was no fever till after the second operation. He had seen a case of Hodgkin's disease in which the fever was intermittent, occurring every five days for a period of twenty days, and on each rise of the temperature there was enlargement of the glands.—Dr. Silver, in reply to Dr. Southey's remark, stated that in the patient referred to by him the earliest symptoms were supposed to be hysterical or choreic, the nervous symptoms being much more marked than the glandular enlargement.—Dr. Southey said that he put the question because he had collected twenty-two cases of lymphadenoid disease, in several of which the nervous phenomena were very marked. In one of the cases the symptoms were at first hysterical, of very pronounced character, subsequently passing into epileptiform attacks.—Dr. Moxon always felt great responsibility with regard to these cases in deciding whether any operative procedure was advisable. He had feared operation on account of the danger of causing acute laryngeal œdema. He referred to cases which were stated to have been cured by the use of arsenic abroad. He himself had used arsenic without effect.—Dr. Glover mentioned the case of a man fifty years of age, who had an enormous glandular mass in the right axilla, great enlargement of the liver, with a contracted, wrinkled condition of the spleen, and anasarca. The remarkable feature of the case was the sensation of great cold of which the patient complained; he inquired whether this had been observed in any of the cases referred to. The thermometer showed no rise of temperature. — Mr. Haward, in replying, said that he had wished to make it clear that he excluded scrofulous enlargement of the glands from consideration; in cases of scrofula there was no doubt a general vulnerability of the lymphatic system, which predisposed to enlargement from slight local causes. Here, however, there was no local condition; it was true that the swelling was first observed soon after an attack of scarlet fever, but the eruption of small-pox was rather a general than a local irritation, and there was no reason why it should be localised in the neck. His object was to inquire how far the removal of the glandular enlargements by surgical means was applicable. Cancer is not cured by removal, but there is often very material relief following such removal, and so also there was in this case. He thought he could remove the whole of the affected glands, and as the disease was a progressive one, he thought the operation justifiable. As to the diagnosis from scrofulous enlargement, he believed that if the glands were so much enlarged from scrofula they would also be caseous, whereas there was no tendency to suppuration, and no implication of the skin. In the earlier stages the diagnosis would be much more difficult. As to the condition of the blood, he had not found any such granules as those described; there were fewer red corpuscles than normal, but no aggregations of smaller globules. The temperature had not been regularly intermittent, there was no elevation above 103 except on one occasion, and it was noteworthy that it was not at all elevated in the early stages. There were no nervous symptoms at any time. He had not tried arsenic in these cases.

MEDICAL SOCIETY OF LONDON.

At the meeting held on the 6th inst., Dr. Routh, President, in the chair, Mr. Maunder exhibited a patient whose elbow had been excised by him seven years ago at the time when he first discovered it was possible in the operation to secure active extension of the triceps muscle, and certainly in this case the extension was very good. Mr. Maunder requested, and the President, with the sanction of the few fellows present, accorded, that the discussion should be postponed to the next meeting.

Dr. Robert Lee brought forward a Pessary invented by Mr. Napier, which he (Dr. Lee) thought was calculated to supersede all others. He also showed a large number of well-known pessaries, and dilated at some length on their advantages and disadvantages from anatomical, mechanical, and physiological points of view. He considered red vulcanite to be the best material for them, and Mr. Napier's pessary is made of that material.—Mr. Napier said his pessary was on the same principle as his catheter, and originated from Mr. Henry Lee and himself. He thought simplicity was a great thing, and considered an elastic substance to be of advantage, as it went well with the movements of the body.—Mr. Henry Lee was of opinion that the defect of most pessaries was that they dilated the muscular fibres of the vagina, and the fibres being dilated were likely to become paralysed.—Dr. Godson stated that he had constantly used a pessary similar in shape to that of Mr. Napier's, though made of black vulcanite and not being elastic, but he had never made use of it except as a last resource, and he preferred the ordinary Zwanke's pessary.—The President was sorry to disabuse Mr. Napier of the idea that his (Mr. Napier's pessary was a new invention, as he (the speaker) had possessed a similar one made of soft india-rubber for ten years; he thought it laboured under great disadvantages in practice, and had found the ordinary Zwanke's pessary to answer very well.—Mr. H. Lee then stated he had tried a common india-rubber instrument and found it of no use. — Mr. Napier said his pessary was not supposed to meet all cases, but that it could be constructed of different sizes.—Dr. Robert Lee briefly replied, and the meeting adjourned.

NEW PREPARATION.

We have received from Messrs. Bullock and Reynolds, of Hanover-street, a sample of a new salt—the citrate of iron and quinetum. Like the citrate of iron and quinine, it is in thin scales, of a greenish golden-yellow colour, and readily dissolves in water, forming a clear solution.

The process of Dr. de Vrij for obtaining all the alkaloids of the East India red bark (to which have been given the name Quinetum), and the introduction of the sulphate by Mr. Whiffin, promise to be of great importance both in commerce and therapeutics. It appears to be well established that every one of the chinchona bark alkaloids is possessed of antiperiodic properties; and quinine is generally considered the most powerful and certain in intermittent and remittent fevers. The relative value of the whole group as they exist in the bark, however, has not been at present experimentally determined, although the presumption is that the alkaloids collectively may prove to be in some respects more efficacious than any one of them when separately employed.

Many practitioners have expressed the opinion that quinine alone does not fully represent the remedial powers of the bark in substance. Is this opinion based upon experience in the employment of these remedies as general tonics and restoratives, or as antiperiodics? The citrate of iron and quinine, for the most part, is employed as a tonic and restorative, and we may fairly anticipate that the citrate of iron and quinetum will be found to equal, if not to excel, in efficacy the corresponding salt of quinine for these purposes. At the same time, a considerable saving will be effected by its use, it being cheaper than quinine; and, as the employment of the latter is much restricted by its costliness, we may hope the introduction of quinetum and its salt will prove a very general advantage.

Poisoning by Mussels.—A man at Dewsbury is stated to have been seized with symptoms of poisoning after partaking of a dish of mussels, purchased from a hawker. Despite the efforts of the doctor called to the case, the unfortunate man died about two hours after the commencement of the symptoms.

THE LANCET.

LONDON: SATURDAY, DECEMBER 18, 1875.

The frightful colliery explosions of the last week or two and the profound grief into which they have thrown the nation, render it necessary to review our knowledge in regard to such disasters, and to inquire what precautions may be adopted and what experiments tried with a view to reducing their frequency and fatality. The present state of things cannot continue. Measures must be found for diminishing the evil, and no economical or commercial considerations must or will be permitted to stand in the way. For not only is the mortality of such disasters terrible in itself and productive of misery in hundreds of homes, but it falls, as scarcely any other calamity does fall, exclusively upon a section of our community to whose labours every individual is indebted.

Fire-damp is a mixture of gases which varies somewhat in composition, but which consists essentially of methane or marsh gas. This is the lightest and most diffusible gas known, except hydrogen. It is not poisonous, is very inflammable, and, when mixed with air, highly explosive. Carbonic acid, the "choke-damp" or "after-damp" of miners, is produced by its combustion. Under ordinary circumstances its flame does not pass through wire-gauze, and hence the protection of the safety lamp; but this valuable safeguard is lost when a rush of explosive gas takes place, or when the lamp is swung violently in the explosive atmosphere. Fire-damp is emitted very irregularly in mines. Some mines are considered safe—a safety which too often proves illusory; while others are known to be "fiery," and even in the latter all calculations are constantly disturbed by the sudden outburst of a torrent of compressed gas released by the blow of a miner's pick.

Of the causes which lead to explosions, some are no doubt due to mere carelessness of employers, or men, or both. It is notorious that the men will, if they can, take the tops off their Davy lamps to get a little more light, even in a fiery mine; and in one of the recent narratives we noticed that lucifers had been found in the pockets of some of the men. Many accidents arise, it may safely be presumed, from blasting. And, lastly, many are led up to by the dangerous assumption that a mine is safe because it has always been reckoned safe. For all such disasters—we will not call them accidents—obvious remedies suggest themselves. The inspection of lamps is already pretty rigidly enforced in all mines, we believe, but the inspection of men should be equally rigid. There are always reckless men who will smoke their pipes in a dangerous mine as they would in a powder magazine, but they must be suppressed in the one case as they are in the other, since they cannot run their risk alone. As for blasting, when blasting is really necessary, and not a mere piece of unnecessary economy, it must be carried out under stringent regulations, and never when the galleries are crowded with men. And, finally, all mines must be assumed to be dangerous if not conclusively proved to be safe.

Of scientific safeguards against explosions, the most important is admitted on all hands to be thorough ventilation. It can never be a complete protection, for some mines cannot be kept free from fire-damp, and the sudden bursts of gas of which we have already spoken set it for a time at defiance; but it is at all times most valuable, not only as diminishing the chance of explosion, but also as tending to localise and diminish the force of an explosion when it occurs. The dangerous work of exploration after an explosion might, we think, be lessened by an application of the Denayrouze apparatus to which we drew attention some time ago; and it is conceivable that respirators packed with fragments of caustic potash might be used for the same purpose. They would, of course, have to be kept ready for use in air-tight cases.

But, after all, further scientific appliances are urgently wanted, and might, we believe, be found, if sufficient diligence were used. What has become of Mr. Ansell's exceedingly ingenious "fire-damp indicator"? We have seen it in use, and can testify to its marvellous delicacy. We are aware of the difficulties which lie in the way of its employment. It is excellent when suddenly brought into the doubtful atmosphere, and will, by the completion of an electrical circuit, carry its indications to any distance—say to an office at the surface; but it becomes inert when it has remained for some time in any atmosphere, good or bad. Nevertheless we do not think it has had a sufficient trial, and should never be surprised to hear that some slight modification had made it all that could be wished as a mere indicator. What is wanted in this direction is an indicator not liable to get out of order, which shall from hour to hour carry trustworthy records of the state of the atmosphere from all parts of the mine to an office on the surface. The responsible man would then know where his immediate attention was required, and if no other good result ensued he would, at any rate, know in any given case whether blasting might or might not be permitted. If Mr. Ansell's apparatus cannot be made to do this, some other might probably be found, and coal-owners would no doubt be glad to co-operate with Government in affording ample encouragement and reward to anyone who could offer even a chance of supplying the want.

The present Coroner for Central Middlesex has held office for a little more than twelve months. He had previously been deputy coroner for as many years; and it is curious to contemplate the resolute manner in which, "armed with a little brief authority," he has shown his disregard for the golden opinions he had won while holding the subordinate post. When Dr. Hardwicke was a candidate for the vacant coronership we gave him our unqualified support because we felt that his conduct as a deputy fully justified his election to the more important office. A reference to the expressions which we used when commenting on Dr. Hardwicke's candidature and election will show that our bias was entirely in his favour, and that nothing but a grave sense of our duty towards the public would be likely to draw from us any strong terms of adverse criticism on his shortcomings. Dr. HARDWICKE had not been in office three months before his want of tact in the matter of Sir CHARLES LYELL's death was spoken of in terms of just rebuke by the Home Secretary in the House of Commons. Commenting on this unpleasant episode, we expressed our opinion that "Dr. HARDWICKE failed in that discretion which is, or ought to be, a principal quality in a coroner"; and that a "few more such errors would destroy the strong public faith in medical coroners." At the same time we expressed a hope that, profiting by his experience, his future conduct would be marked by more discretion. The delusive nature of this hope was, we are sorry to say, amply demonstrated before Dr. HARDWICKE had been three months more in his office; and it was in May that he made the wholly unwarrantable statement that, in a certain case, "the conduct of the medical officers was simply atrocious." Reviewing his conduct upon this occasion we observed that the gentleman whose conduct was called in question was, in our opinion, in no way deserving of censure, and that "the Coroner's remarks were not only unnecessarily harsh, but calculated to mislead the public, whom soberly to instruct is one of the coroner's duties." Again, in May, we find Dr. HARDWICKE holding an inquest at St. Mary's Hospital on a cabman who had fallen dead off the box of his cab, and, without calling the medical man who had attended him, and without a post-mortem examination, allowing a jury to return a verdict of "Death from natural causes." For the next five months the Coroner's conduct was not publicly called in question; but in November we hear of his encouraging a jury to censure a medical man for contempt of court, when he ought to have known that only his own beadle was to blame. The murmurings of disapproval have scarcely died away when the name of Dr. HARDWICKE again becomes prominent; and it is a singular and an unfortunate fact that this last resembles the previous cases, in that the Coroner is found in unfortunate collision with the members of his own profession, towards whom he has systematically behaved with marked discourtesy under a mistaken notion probably of publicly exhibiting his impartiality towards all classes. The facts of this last case are briefly as follows.

An eminent member of our own profession, Mr. ACTON' who had just entered his sixty-third year, had been for some months past in failing health. This was a fact well known in his own circle. On Sept. 29th he fainted in the streets, and was brought home by a policeman in a cab. This warning was not lost upon the deceased, who at once set to work to settle his affairs and leave his estate in order for his executors. At the same time he consulted Sir JAMES PAGET, Dr. MURCHISON, and Dr. QUAIN respecting his health; and we believe these high authorities concurred in the opinion that Mr. ACTON was the victim of heart disease. Dr. MURCHISON might be looked upon as his ordinary medical attendant, but, Mr. ACTON himself being a medical man, Dr. MURCHISON only saw him occasionally, the last time being in October. On the morning of Dec. 7th Mr. ACTON was found dead in his dressing-room, and his family summoned their nearest neighbour, Dr. HALL DAVIS (who had not, however, been consulted by Mr. ACTON during life), whose melancholy duty it was merely to inform them that life was really extinct. On December 8th, Dr. MURCHISON, assisted by Dr. CAYLEY, made a post-mortem examination, the result of which was to verify beyond question the diagnosis which had been made during life. In the meantime, however, the Coroner, through his beadle, had made arrangements for an inquest, and had deputed Dr. HALL DAVIS (who had never seen the deceased professionally during life, and consequently knew nothing of his condition except by hearsay, and whose devotion to obstetric medicine causes a post-mortem examination to be to him a prohibited duty) to make the post-mortem and give the necessary evidence. Dr. HALL DAVIS deputed Dr. CAYLEY to make the post-mortem, and these two gentlemen both agreed with Dr. MURCHISON as to the cause of death.

Now here we have the case of a medical man, whose condition had been diagnosed during life by the heads of the profession, dying of the disease which had been diagnosed, and the diagnosis further confirmed by a post-mortem and microscopic examination by two persons than whom none are better qualified in the profession to come to a proper conclusion on the matter.

After the post-mortem examination the following certificate was furnished by Dr. MURCHISON:—

"This is to certify that William Acton, aged sixty-two last birthday, repeatedly consulted me during his lifetime for symptoms of heart disease; that I last saw him in October; that he died on December 7th, at 17, Harley-street; and that the cause of his death was fatty degeneration of the heart, confirmed by post-mortem examination."

If the circumstances attending Mr. ACTON's death were such as to justify a coroner's inquest, then we say advisedly that we cannot conceive any circumstances under which an inquest would not be justifiable.

To continue our narrative. Since the Coroner had issued his order for the inquest, Mr. ACTON's son took the above certificate to the Coroner, in order, if possible, to avert what could not be but a painful proceeding to his family. The Coroner's conduct, when confronted with the certificate, is, to say the least, instructive. He informed Mr. ACTON jun. that he was unable to accept the certificate unless they would do so at the Registry Office; and at the Registry Office this gentleman was informed that, since the Coroner had issued his order for an inquest, they dared not accept the certificate under pain of a heavy penalty. The Coroner, not seeing fit to countermand his order for an inquest, the inquest was accordingly held; and we understand that Mr. ACTON has, in the most public-spirited manner, brought the whole matter officially under the notice of the Home Secretary, who, probably, will forward the facts for the Lord Chancellor's perusal; and it remains to be seen whether Mr. CROSS or the Lord Chancellor is capable of holding in check that excessive zeal which has now on too many occasions proved harassing and vexatious to the inhabitants of Central Middlesex.

◆

IN the first of the two letters with which Dr. JOHN SUTHERLAND has recently favoured us (THE LANCET, Nov. 7th), the attention of our readers can hardly fail to have been arrested by the following sentences:—"In the whole history of human progress there is nothing more remarkable than the advance of sanitary improvement in India during the last ten or twelve years. There is nothing in the West that can be compared with it. The work is far from being done; but very much has been already accomplished." If this view of the progress of sanitary work in India be right, it should serve as an additional incentive to sanitary workers in this country to bestir themselves, so that at least sanitary improvement here may keep abreast of sanitary improvement in India, if it may not hope to keep in advance. If the view be wrong, it is necessary that it should be corrected, lest delusive conceptions of work accomplished should aggravate the mischief arising from such faulty methods of work in India as we had occasion to direct attention to last week (THE LANCET, Dec. 11th). At all times we have never failed to acknowledge and express our admiration of the greatness of the sanitary work done by the Government of India since 1864; but we have been accustomed to measure that greatness by the peculiar difficulties it has had to overcome, not by comparison with work done in this country. But Dr. SUTHERLAND, in the interest of the Army Sanitary Commission, now challenges this comparison; for we presume that his reference to the West really means to this country, any other comparison being, so far as we can apprehend, purposeless. It is difficult to approach the discussion of the question thus raised with gravity. In England, from 1848 to the present time, the whole aim of sanitary legislation has been the development of local sanitary self-administration. Every step in legislation since that date has been the result of a growing desire on the part of local authorities to possess additional powers for dealing with matters relating to the public health; and the Public Health Act of 1872 made a notable step to the completion, on the administrative side, of this steady process of local governmental education in sanitary matters. Parliament, indeed, has lagged behind rather than kept in advance of public feeling on these subjects. Sanitary work has progressed in due proportion to the progressive education in local sanitary government, marked by the growth of sanitary legislation. The amount of work done, measured by a cost of millions of money, is unimportant compared with the fact of its doing and maintenance having depended on the action of the people, or rather the ratepayers themselves. Turn we now to India. It is to the honour of the great administrators of that Empire that they have held that true sanitary progress among the populations of India will, as a rule, best be secured in proportion as it can be based upon a principle of local administration analogous to that developed in England. This view, we believe, has been steadily maintained by successive Viceroys, and its development has at all times been regarded as of primary importance in the working of the present sanitary organisation of that Empire as it affects the civil population. But what has been accomplished? Under an impulse dating from the Royal Sanitary Commission of 1859, and primarily relating to the health of the army in India, and by an expenditure wholly Imperial, this has been done: The army has been put into a healthier state; and a commencement has been made, by the appointment of sanitary commissioners for the different provinces and capital cities, of an organisation for the sanitary administration of the civil population. We have brought, at an enormous cost, under decent sanitary control the British army in India—numbering, say, 70,000 men; we have made a respectable beginning of getting under like control the Native army—say of 130,000 men; we have started sanitary works, on European models, in the capital cities of the Presidencies, with their collective population of, say, 2,500,000; and for the balance of the population of India—say 180,000,000—we have provided some twelve sanitary commissioners for provinces and a few medical officers of health for big towns, and have through them induced local sanitary action at a few points, and have regulated religious and other fairs. We have also promoted vaccination. This is the kind of result which, it is to be inferred from Dr. SUTHERLAND's letter referred to, the Army Sanitary Commission holds to surpass sanitary progress in this country—that is to say, the West. If this be the view of the Army Sanitary Commission, it proves that it mistakes the actual position of sanitary progress in India, as it has mistaken the requirements of sanitary investigation and work.

Indian sanitary work can well afford to stand upon its own merits. To claim for it other credit than that which properly pertains to it is to prejudice it in the minds not only of this country but of other nations. The difficulties which beset sanitary administration and work among the civil population of India are much too serious that it should be attempted to veneer them with fallacious comparisons. It must be sufficiently difficult already, we should imagine, having regard to the proceedings of the late International Sanitary Conference, for the Indian Government to satisfy Continental Powers that it is doing not only all that was practicable for it to do, but all that could, with certain reservations as to method, reasonably be required from it in sanitary works, without having to contend with obstacles raised by its own advisers.

Annotations.

"Ne quid nimis."

OVERWORK AT SCHOOLS.

THE letter written by the Rev. Frederic W. Farrar, which appeared in the *Pall Mall Gazette* of the 14th inst., confirms our statement that at Marlborough, as at other first-class schools, the hours of work are not excessive. Mr. Farrar says "the time spent in our school by any boy only amounts to twenty-six hours a week, and, even with the necessary preparation of lessons, falls very far short of the forty-five and forty-eight which are required at some schools." Marlborough has a high repute for scholarship; its boys do well at the universities, and in the competitive examinations for the Civil Service and Army there are few schools which can show greater measure of success. Yet this is attained without any undue pressure or forcing. The secret of this success lies, no doubt, in the method of teaching adopted. And, as we have said before, the more closely the old public school traditions are adhered to, the sounder will be the system of education, and the greater will be the ultimate success of the scholars. Our remarks have been considered to have pressed hardly on the masters of the schools censured for working their pupils eight to nine hours a day; and it is urged the fault lies with the Government and with the examiners who require so high a standard of excellence in such a multiplicity of subjects that cramming becomes a necessity. We hold, however, to our first opinion. We have seen how, at the chief public schools and at well-managed proprietary colleges like Marlborough and Cheltenham, considerable success at these examinations can be attained with a moderate amount of work; and we are sure, wide as is the range of subjects required by the majority of competitive examinations, they are within the grasp of the intellectual capacity of the average schoolboy if properly taught him. And we believe that examiners are learning to discriminate between a thoroughly taught and gradually matured mind, and the ill-digested masses of information acquired by the pupil of the grinder. We believe the real fault lies with the parents, who insist that their sons shall have "every advantage"; hence Greek, Latin, French, German, mathematics, drawing, modern history, ancient history, ditto ditto geography, chemistry, botany, natural philosophy, philology, &c., are poured in at the rate of so many hours a day, utterly regardless of the boy's natural bent or capacity. A few boys with retentive memories retain some smattering of this farrago of learning, and achieve some success, which, duly advertised, renders other parents anxious to join in this "fetish worship," more especially as the school possessing "every advantage" is often also more economical than the public schools or the higher class of proprietary colleges. The extent to which the evil is carried on, especially in the neighbourhood of London, is extraordinary. A gentleman connected with an educational establishment of high standing, and who has often spoken with authority on educational questions, considers the subject to be worthy of Government inquiry. Only a Royal Commission could get at the real truth and reveal the amount of mischief that has been done by the reckless employment of the grinding system. In the same manner that factory children are protected from excessive physical labour ought the children of our middle-classes to be protected from excessive strain that ambitious parents and schoolmasters would put on them. It should never be forgotten that youth is the period of growth and development, and that the boy is then laying in the stock of health which has to bear him bravely through the vicissitudes and struggles of adult life. A few hours of work can speedily be made up later on, but nothing can restore the tone to the jaded nerves exhausted by premature toil and excitement.

ALCOHOL AS A MEDICINE.

A DIFFICULT question in medical casuistry was suggested the other day at an inquest held by Dr. Diplock. An infant died under the following circumstances. After two days' illness, during which only some medicine from a chemist had been administered, Dr. Woolrych was sent for, who found the child suffering from an acute lung affection, and ordered that the child should have brandy and milk. The father refused to give the child brandy; he was a total abstainer, and "did not believe that it would do any good." Dr. Woolrych then declined to attend the case. Another medical man was sent for, but before he arrived the child was dead. Dr. Woolrych was asked by the coroner whether he suggested any other stimulant, such as ether or chloroform, and replied that he did not. It was impossible to say that brandy in this case would have saved the child's life; indeed, it is obvious that the child was already past hope. Accordingly an open verdict was returned. The wider question, however, is raised, Is a medical man justified in withdrawing from a case in which his directions as to the administration of stimulants are openly repudiated? Ought he to refuse his help, or should he endeavour to replace the obnoxious brandy by other stimulants—ammonia, ether, chloroform? It is doubtful how far these stimulants can take the place of brandy. Their effect is different; their action produces other secondary consequences more deleterious than those of ethylic alcohol. They cannot be substituted for wine or brandy. They may supplement, but cannot replace the latter. A case could not be treated on such conditions without deliberately accepting an inferior vantage ground for the contest with disease. It is certainly a course more consistent with self-respect, more consistent with due regard for the wider interests of humanity, to decline to undertake the treatment of disease weighted with such needless and prejudicial conditions. It may be suggested that the difficulty might be in many cases overcome by administering alcohol under the guise of physic. But this is a deliberate deceit, and it would be better to decline the management of a case on such terms, and to allow the responsibility of the results to rest where it is deliberately assumed.

THE HARVEIAN LECTURES.

THE second of these lectures, on Bright's Disease considered in relation with arterial tension from blood contamination, was delivered before the Harveian Society on Thursday, the 9th inst., by Dr. Sibson, to a numerous and appreciative audience. The greater part of the lecture was occupied in the demonstration, by means of the oxyhydrogen lamp, of the sphygmographic tracings of the pulse in cases of the different forms of Bright's disease under varying conditions of pressure and tension. Of these, although of great interest, it is impossible to give any idea without the aid of diagrams. Dr. Sibson exhibited a sphygmoscope which he has long used to estimate the pressure in the vessels, and also a modification of the sphygmograph, in which, by means of a screw, the pressure can be more easily and rapidly regulated than in Dr. Sanderson's modification of Marey's instrument. In the latter portion of the lecture Dr. Sibson took up the subject of treatment, classifying the therapeutic measures under three heads. These were, first, to promote the elimination of the effete products from the blood by the various channels; second, to avoid the introduction of other poisonous material which could tend to aggravate the condition of the blood; and, third, to enable the patient to live above and in spite of the blood condition. To fulfil the first indication, the ordinary measures were recommended. Under the second heading, Dr. Sibson dwelt especially on the importance of feeding the patient on substances which are free from the products of tissue oxidation and yet afford a great amount of nourishment; and on this ground he strongly recommended milk as a diet in preference to beef-tea, the latter containing so large a proportion of extractive matter. The drinking of pure water, such as Malvern water, or of soda water in quantity, was also advised. On the other hand, the lecturer eloquently enforced the danger of administering alcohol in such cases; he regarded it as only adding fuel to the fire, and overloading the blood with a poison which in itself is liable to set up similar changes in the blood and vessels to those induced by the morbid poison of Bright's disease. He allowed, however, that in some cases the administration of alcohol seemed to give tone to the system, and enabled it to excrete the morbid materials more readily. The employment of opium or morphia, whether subcutaneously or otherwise, was justly condemned in strong terms in cases where there are albuminuria or signs of renal and vascular degeneration; and the lecturer urged the importance of examination of the urine before the administration of these drugs.

Finally, in order to enable the patient to live above the influence of his disease, Dr. Sibson strongly recommended that plenty of exercise should be taken, since the muscular action not only enables the heart to perform its work with less effort, but promotes elimination. Cheerful society, healthful bodily and mental work were, he considered, far better than inaction, for by means of them the healthful balance of function and the mutual reaction of organs might be maintained even with a partially diseased organ, and the patient be thus in a state of relative, if not of actual health. Dr. Sibson concluded an interesting lecture by thanking those who had enabled him to undertake and assisted him in a course of investigation at various hospitals, which had extended over many months.

THE OPPONENTS OF THE CONTAGIOUS DISEASES ACTS AGAIN.

WE gather from the *Folkestone Chronicle* that the agents of the Society for the Abolishment of the Contagious Diseases Acts recently convened a meeting in that town, with the view of getting a public expression of opinion adverse to the Acts in question. If the opponents of these Acts were content to address their appeals and arguments to those to whom they should be limited, we should be content to leave this subject alone, and to accept the verdict of impartial persons of reflection in regard to it, but we must strongly protest against the course that is now being adopted. We learn that during the day of the meeting "bills of a most objectionable character were circulated about the town and put into the hands of young girls, in which they were asked to attend." There was a large gathering of males, including a number of the more respectable inhabitants, but we are glad to learn that no female was present at the meeting. The attempt on the part of the deputation from the Association for the Repeal of the Acts was a miserable failure—indeed, the tables were completely turned on them, for the amendment in favour of the Acts was carried all but unanimously. The deputation might have known what to have anticipated from the fact that the inhabitants of Folkestone have had an opportunity of observing for themselves what has been the effect of the working of the Acts in their neighbourhood, and many of those at the meeting were well acquainted with the subject, especially Dr. Gill, who replied in the most effective manner to the statements and reasons adduced by the deputation. To borrow the words of our contemporary, "in no town have they been so entirely snuffed out as in Folkestone." The Mayor, very rightly, refused the deputation the use of the Town Hall, and we heartily concur with the *Folkestone Chronicle* in believing that "such agitations against these Acts are thoroughly unjustifiable and indecent."

OFFICIAL WORRY.

IF we were asked to assign one cause as more potent than another, or possibly than all the rest put together, for the existing discontent among army medical officers, we should have no hesitation in referring to the state of worry and irritation brought about by constant changes. This has been going on for years past. What with the constant succession of new or amended warrants, regulations, army circulars, and what not, nobody knows exactly where he stands or what he is to do. This worrying system seems to have affected all branches of the public service more or less. We recently saw it aptly remarked somewhere that the Government treats a public service exactly as a schoolboy does the seeds that he has sown in his garden; he is for ever digging them up to see how they are getting on. Let anyone address himself to the first half dozen men belonging to as many public services, and what will he hear? That everything seems to be for ever changing, and nothing fixed; that regulations are like words writ in sand—gone before you know where you are! To-day a Liberal wave effaces this, and to-morrow the Conservative reaction re-established that; while a host of minor officials belonging to both parties, or to no party at all, seem to employ themselves in giving a new or different meaning to what is the natural one to everything they come across. The army medical service is organised on neither a regimental, general, nor any other basis at present; but a sort of hybrid system exists which pleases no one, and those charged with its working are loud in their complaints that their rights and privileges have been curtailed or abrogated altogether. The last regulations as to the issue of forage or forage allowance will be sure to add to the discontent. We question whether it will be found practicable to carry them out, and, so far as we can discern, nobody will be benefited by the new ruling that duty and not rank is to be the officer's only title to forage, unless it be the equestrian statues in London, and they may fairly claim a title to a forage allowance inasmuch as they are "permanently mounted."

THE PRINCE AND THE DOCTOR.

OUR contemporary, the *Examiner*, recently devoted an article, under this heading, to the sudden and unlooked-for check which the triumphal progress of the Prince of Wales through India had experienced. Dr. Fayrer, the medical ruler of the expedition, having heard that cholera had shown itself in some parts of Madras, issued an edict tabooing, it said, the "benighted presidency." Here lies cholera, there lies cholera: at Coimbatore and Bangalore, at Madras and Pondicherry, wherever the inhabitants of the "benighted presidency" do congregate, our contemporary went on to say, the scourge of the East is uplifted, and the doctor puts his veto on the projected excursion. Our contemporary agrees with everybody that Dr. Fayrer was only discharging his duty, if cholera existed in Madras, by putting the presidency under the ban; but it goes further, and points out that Dr. Fayrer has evidently not yet learned to discriminate between the two forms generally assumed by the disorder in the East. Of epidemic and endemic cholera there is little fear, the season having advanced too far for an outbreak; and as to the sporadic type, now or until very lately existing at Madras, that may be found in almost every great Indian city at all seasons of the year. Dr. Fayrer will probably be amused, if not instructed, by the points of contrast between the two forms of cholera indicated by our contemporary, should he happen to read the article in question. It is neither an impossible nor a very improbable conclusion, however, to assume that a physician who has spent all his life in India will have already learned anything that the article in question is capable of teaching him. Meanwhile, the Prince's arrival in the "benighted presidency" has been announced, although of course our contemporary was at the time quite justified in regarding it as very improbable that such would be the case.

THE KEIGHLEY GUARDIANS AS HYDROPATHISTS.

Now that the Keighley Guardians have lost the excitement of antagonism to law and common sense, by abandoning their opposition to the Vaccination Acts, they are to be invited to other displays of the art of mixing up the two functions of guardians and doctor. "The chairman," we read, at a recent meeting "gave notice that he would, at the next meeting of the board, bring forward a motion for the purpose of getting the board and the medical officer of the north district—Mr. Roberts—to co-operate in treating patients hydropathically." Why "Mr. Roberts, of the north district," should enter into this sort of medical partnership with the guardians is not stated. We have one amendment to make on this suggestion of the chairman.

We should propose to substitute for the word "patients" the word "guardians." We could imagine nothing better for the guardians of Keighley than cold-water treatment. They have had a good deal of cold water thrown on them lately by the Court of Queen's Bench, by other boards of guardians, and, most of all, by a few sensible members of their own board. We should not, however, object to see them subjected to hydropathic treatment by Mr. Roberts; but we should decidedly protest against the paupers being subjected to hydropathic treatment, the result of co-operation between the guardians and Mr. Roberts. If Mr. Roberts thinks any of his patients want any particular form of treatment, he will doubtless see that they are supplied with the means of applying it; but on the mere instigation of the chairman of the Keighley board, to "occasionally" give paupers, in the hard conditions of winter, a turn of hydropathy, is a proposal which seems to us to deserve watching by the Local Government Board. Things must have come to a pretty pass in the Keighley board when the chairman has to suggest the treatment of patients to the medical officer! What next?

THE EPIDEMIOLOGICAL SOCIETY: CHOLERA IN SYRIA.

At the meeting of the Epidemiological Society, on the 8th instant, the President, Mr. Netten Radcliffe, in the chair, a paper was read communicated by Dr. Wortabet, of Beyrout, on the recent outbreak of cholera in Syria. The paper dealt rather with the manifestation of the disease in Beyrout than with the general distribution of the epidemic in Northern Syria. It threw no light upon the origin of the outbreak, and the author maintained a judicious reserve upon this question, hesitating to express an opinion where the information was so imperfect. In the discussion which followed, and in which Mr. Cornish, the Sanitary Commissioner for the Madras Presidency, Mr. C. Macnamara, Inspectors-General Dr. John Murray and Mr. R. Lawson, Dr. Thorne Thorne, Dr. William Squire, and others, took part, the subject chiefly considered was the data which existed regarding the origin of the outbreak. These were so imperfect that it was obvious discussion was idle, and more than one speaker protested against certain speculations which were already being indulged in as to the so-called *de novo* origin of the disease. Mr. Macnamara especially showed how, in regard to other outbreaks of cholera, long regarded as indicating that the epidemic disease could have birth elsewhere than in India, that they were filiated with the malady prevailing elsewhere. Some interesting remarks on the question of the dormancy of epidemic diseases were made by Dr. Thorne Thorne and Dr. William Squire.

THE EFFECT OF COLD WEATHER UPON MORTALITY.

The mean temperature was continuously below the average during the twenty-two days ending 11th inst.; at the Royal Observatory, Greenwich, the mean for this period was no less than eight degrees below the average. The mean temperature of the week ending 4th, was more than a degree below freezing point, a lower temperature than in any week during the cold weather in November and December last year. The rate of mortality in English towns, however, does not hitherto show nearly the same excess as prevailed at this time last year. During the five weeks ending 27th November, the rate of mortality in eighteen of the largest English towns had been remarkably stationary, and averaged 24·1 per 1000, whereas in the two weeks ending 4th and 11th inst., the rate increased to 25·9 and 28·1, respectively. In London the rate in the five weeks ending 27th ult. averaged 23·4, and has been equal to 24·7 and 28·1 in the two subsequent weeks. From published metereological returns it appears that the temperature has recently been lower in London and Bristol than in the more northerly towns, and hence the death-rate has shown, in the past two weeks, a higher percentage of increase in the metropolis than in the seventeen provincial towns. According to the Registrar-General's last published weekly return, the death-rate in London from diseases of the respiratory organs was equal to 7·7 per 1000 in the week ending 11th inst., against 4·6 in the five weeks ending 27th ult., thus accounting for about two-thirds of the excess rate from all causes, which was equal to 4·7. It it worth notice that in spite of the recent cold weather the death-rates in Leeds, Sunderland, and Newcastle-upon-Tyne, have steadily declined during the past three weeks in face of a large increase in most of the other towns.

THE CATASTROPHE AT NORWICH HOSPITAL.

There is but little to add to the details contained in the local papers of the late terrible occurrence at Norwich Hospital, but at the moment of going to press we have received a few additional particulars. The three unfortunate lads who were murdered had their heads simply crushed and smashed by repeated blows with the tongs, the weapon used by the alleged murderer. A fourth boy, named Clarke, a patient of Dr. Eade's, has lost the slight sign of rallying that was manifested, and a fatal issue is feared. He is suffering from a fractured skull, and has been unconscious from the first. The fifth lad, also a patient of Dr. Eade's, has a battered and injured skull, but is much less seriously hurt, and it is confidently hoped that he will survive his injuries. It does not appear that any blame is attributable to anyone—certainly not to those in the hospital. But for the very gallant and determined stand which the house-surgeon made against the frenzied man the consequences, already so terrible, might have been frightful to contemplate, and we think his conduct deserving of the greatest praise.

FLOCKS.

A correspondent of the *Glasgow Herald* has called attention to a hitherto unsuspected source of disease. For stuffing beds and furniture a substance called "flocks" is in common use, and the source and character of this material are, it is said, such as to render it a most undesirable material for the purpose, and one not unlikely to be a ready and effective vehicle for the conveyance of contagion. The flock manufacturer collects rags of every kind, and for the most part of the most filthy material, "the pickings of ash-pits, the worn-out clothes of all classes, including the cast-off greasy tatters of the denizens of the slums and wynds of our towns and cities," and this material is, it appears, made up into flocks without any preliminary purification. The rags are dried, passed over revolving rollers with prongs of teeth, which tear them down to fibrous consistence, clouds of dust flying from them and passing up chimneys, to darken the air, and cover the surface of the neighbouring land and houses.

There are, however, we believe, flocks and flocks—white flocks and black flocks, and the description we have quoted of the source of the material employed is true only of the coarser variety of black flocks. It is indeed a loathsome substance—the rags from which it is made, and often the "flocks" itself, swarming with animal life, and it is utterly unfit to be employed for stuffing any article of furniture, far less bedding. But the "white flocks" is a very different substance; the best is a pure white soft cottony material, the product, we believe, of an Indian plant. It is preferable, in fact, to the imperfectly preserved and often not inodorous feathers, which are often put into beds. The black flocks is likely to be a grave source of disease, and we agree with the correspondent whose letter we have quoted, that its use should be conditional only on absolute purification. The matter is one which deserves and should receive the immediate attention of the sanitary authorities of the districts in which flock-mills are situated. We are not surprised to learn that the manufacture is a most unhealthy one, the health of the workpeople suffering very seriously from the contamination of the atmosphere produced by the flying particles of impurity.

ST. THOMAS'S HOSPITAL.

UGLY rumours have long been abroad of the persistence of typhoid fever among the resident staff at St. Thomas's Hospital. Although some of the accounts have been exaggerated, there is a considerable element of truth in the reports. It is not, for instance, true that many of the nurses and dressers have died of typhoid fever contracted in the hospital, but there have been within the past twelve months three or four deaths from typhoid fever. Some months ago typhoid broke out in the apothecary's house, and a search showed, we believe, that there was some faulty drainage, but this has been put right. It will be remembered that a dresser died a short time ago in the hospital of typhoid fever, and we took the opportunity of calling attention to the wretched and dirty condition of the small rooms in which the dressers were expected to sleep at night and to occupy during the day. Something has been done to make these chambers more wholesome and habitable. At present typhoid seems to have attacked the nurses. The night superintendent died recently of the fever, and a sister and a nurse are now ill with what is believed to be typhoid. How this disease has been contracted is a problem which the Committee of St. Thomas's would do well to submit to its medical staff for solution.

THE TOUR OF THE PRINCE OF WALES.

ACCORDING to the latest written intelligence received by us of the Prince's tour, dated the 21st ult., His Royal Highness left Bombay on the 17th, and went to Baroda in excellent health, as were all the party. After all the ceremonies and parades of Bombay, the Prince enjoyed his cheetah hunting and black buck shooting, and has hitherto stood the heat as well as, if not better than, most English new comers. Lord Charles Beresford's accident at Poona was only a bruise, of which he soon recovered. His Royal Highness visited the European Hospital at Bombay, and it is to be hoped that some good may arise from this circumstance, as several of the defects of that institution were brought to his notice. The reports of cholera were so rife from Madras at the date of our correspondent's writing that it was deemed advisable to defer His Royal Highness's visit for a time.

UPPINGHAM SCHOOL.

THE question has arisen as to the reopening of the Uppingham School. The sanitary authority of Uppingham report that the condition of several of the school-houses is such as to necessitate material alterations in their sanitary arrangements, and they discountenance a return of the scholars until these alterations have been effected and each individual house in connexion with the school is put in a perfect sanitary condition. We agree with Mr. Rawlinson, the Government inspector, that till the plans, reports, and estimates are submitted to him for his approval, it is "premature to publish any statement relative either to the state of the town or to the state of the schools." But surely it is equally premature to allow the return of the boys before the official statement of the causes leading to the outbreak has been made public, and the assurance given that all sanitary defects have been remedied. We strongly advise parents not to allow their boys to return to the school till they have received this assurance from the report of the Government inspector, who alone has the responsibility of speaking authoritatively on this point.

THE HOSPITAL SUNDAY FUND.

THE Council of this fund met on Friday, the 10th inst., under the presidency of the Lord Mayor. It is gratifying to have to notice that the new Lord Mayor displays a personal interest in the institution of Hospital Sunday. The meeting was well attended by clergymen and laymen. The fact that the sum collected this year is less by £3000 than that collected last year, was satisfactorily explained by two simple circumstances—viz., that the day of collection was a very wet one, and that some unfavourable feeling had undoubtedly been raised by the unseemly action of the representatives of special hospitals in the beginning of the year. Now there is practical unanimity on most points, and the distribution of this year has given satisfaction, except to those institutions which used to receive more from local collections than they do from the fund. These institutions are very few in number, and their claims are comparatively slight, so that it would be an act of policy as well as justice on the part of the Council to see that they are indemnified out of the fund for the loss of local collections. The object the Council should aim at is to liberate the clergy for a great, hearty, and consentaneous appeal that should supersede the petty appeals for local medical institutions.

THE SANITARY CONDITION OF NORTHFLEET.

WITH reference to our remarks on this subject in a recent issue, we have received a communication from the Board of Guardians of North Aylesford, disclaiming all responsibility for the sanitary condition of Northfleet. It appears that subsequent to the passing of the Public Health Act of 1872, by which Northfleet was constituted a part of the rural sanitary district of North Aylesford, that parish was, in June, 1874, created a local board district. The local board of Northfleet, therefore, now constitutes the urban sanitary authority for that parish. The thirty-nine deaths registered in the parish and local board district of Northfleet during the three months ending September last were equal to an annual rate of 23 per 1000 of the population, estimated at 6874, and included ten, or 26 per cent., which were referred to the seven principal zymotic diseases, of which five resulted from whooping-cough, two from fever, two from diarrhœa, and one each from small-pox and measles. We can readily understand that the North Aylesford guardians are glad to be able to repudiate any responsibility for the present sanitary condition of Northfleet, and trust that the local board, the present sanitary authority, will be as ready to take measures to improve the health of the parish.

THE WARNING SYMPTOM OF SLEEPLESSNESS.

IT is of course premature to offer any remarks on the "Tragedy at Norwich," but there can be no objection to urging very strenuously upon hospital surgeons and practitioners generally, who are not specially familiar with the symptoms of mind and brain disease, the imperative necessity of treating "sleeplessness" as a warning symptom. A "curious patient," so described because he does not sleep, should be at once placed under proper supervision, for his own sake and the safety of those around him. Inability to sleep is one of the most significant indications of a condition of nervous irritability or mental excitement which may at any moment assume the form of uncontrollable violence. Delirium tremens, traumatic delirium, and the most dangerous forms of mania are all prone to give this warning token of their presence, and scarcely any other. Without in the least prejudging the case now *sub judice*, we venture to bespeak the attention of the profession and the public for a matter of daily importance, unfortunately impressed afresh upon the notice of everybody by this terrible lesson in blood.

THE CHAIR OF PHYSIOLOGY AT GLASGOW.

THE candidates already in the field for this important scientific appointment are Dr. McKendrick, and Dr. Eben Watson. The former gentleman is assistant to the Professor of Physiology in Edinburgh, and is well known as the author of many excellent original papers which have been published in the Transactions of the Royal Society, and which constitute permanent and important steps in the science to which he is exclusively devoting himself. Dr. McKendrick possesses unusual power of exposition as a lecturer, and his claim is at least deserving of all consideration by the Secretary of State whose duty it is to advise the Crown in these matters.

SIMLA.

COMPREHENSIVE and energetic efforts will shortly be made to improve the sanitary condition of Simla, the favourite resort for European invalids, civil and military, at the foot of the Himalayas. The system of drainage, long known to be defective, will be thoroughly revised, and water will be brought into the station from a distance of ten miles. It is estimated that the required improvements will necessitate a cost of at least £100,000; but it will be money well spent. The fever-stricken traveller from the plains, who gazes on the "Abode of Snow" as a veritable Canaan, will no longer be disquieted by reports that the water in Simla is as bad as that he has left behind, and that on rainy days the streets overflow with liquid sewage.

THE ROYAL COMMISSION ON VIVISECTION.

THE Royal Commission on Vivisection, which has sat every day this week, has now practically finished its labours. The report of the Commission cannot, of course, be made public until it has been presented to Her Majesty the Queen, and laid upon the table of the House. The standing and influence of the Commissioners, and the thoroughness with which they have fulfilled their duties, may be taken as a guarantee that the recommendations they make will prove acceptable to the medical profession, and not distasteful to the more sensible anti-vivisectionists.

FEVER AT CROYDON.

IN answer to the memorial of the inhabitants of Croydon, requesting that a Government inquiry should be held respecting the causes leading to the epidemics of enteric fever with which Croydon has been visited this year, the Local Government Board have instructed Dr. Buchanan to make the necessary investigation. Permission also has been sought to borrow the sum of £14,100 to extend the waterworks and furnish the town with a constant supply. Last week we announced that an important discovery had been made that the large overflow pipe of the cistern communicated directly with the sewers, and so permitted the sewer-gases to have direct access to the water of the cistern. Disgusting and disgraceful as this arrangement must be considered, it can hardly in itself be held sufficient to account for the epidemic, though drinking a water charged with sewer gas may be considered, no doubt, as a highly predisposing cause. The history of past epidemics has shown conclusively that the disease is spread by the *actual* presence of fæcal matter, specifically contaminated, in the water itself, so that we must continue to hold the opinion originally expressed by us, that the cause will be found to lie in a defective condition of the sewers and water-mains at one or more points; the contents of the former passing into the latter when the supply is intermittent.

IN a short memoir which Sir Thomas Watson has written of the late Dr. Peter Mere Latham, who had outlived nearly all his contemporaries, he states that his conduct throughout life was governed by an abiding and imperative sense of duty, and as a corollary of this temper of mind must be reckoned his love and habits of order and method. The letters received by him and kept were all arranged in packets, and the substance of each was noted on the envelope. He was a charming companion, full of various information, affluent in anecdote, with a keen sense of fun and humour, and with this was blended a quick susceptibility of pathetic emotion. "Ripe in years as he was, and ready in spirit for the solemn change, his death must long be the subject of tender and sacred regret among the nearest and dearest of his surviving family and friends; nor will his memory soon cease to be reverently cherished throughout a much wider circle.

'Multis ille bonis flebilis occidit,
Nulli flebilior quam mihi.'"

THE authorities of the *Cornwall* are unable to take advantage of the offer made to them by the Admiralty of H.M.S. *Clio* on account of the heavy attendant expenses. It is now arranged that the *Cornwall* shall be moved down to Gravesend as soon as possible, and be there thoroughly cleaned and refitted. The propriety of retaining the permanent moorings at Purfleet is still under consideration, and we are informed that the port medical officer has advised the *Cornwall* authorities to ask for an opinion from the medical department of the Local Government Board as to the possible evils likely to arise from the comparative proximity of the ship to the metropolitan main drainage outfalls. There is now so much difficulty in finding berths for ships of this class in the Thames that the removal of the *Cornwall* from Purfleet might possibly result in the breaking up of this School-ship Society.

DR. WHITMORE, medical officer of health for Marylebone, in his monthly report of the health of the district during November, observes that the deaths from bronchitis, pneumonia, and heart disease have increased with the advent of the cold weather, while scarlet fever still continues its ravages. Dr. Whitmore urges the adoption of a more efficient system of street cleansing than that now prevailing. This is a subject which might well be taken up by the vestries of the metropolis before we have another fall of snow, with the inevitable amount of mud and slush.

NUMEROUS complaints have been made within the last few months of the condition of the water-supply in Gibraltar, and the allegations of its impurity have been so persistent that samples were sent to London in order to be analysed. The result of the analysis proved conclusively that the water was unfit for consumption. We hope that, in consideration of the health of the troops in quarters, no less than of the inhabitants, the Sanitary Commissioners of Gibraltar will lose no time in devising means for securing an improved service of water.

At a meeting of the Council of the Poor-law Medical Officers' Association, held in October last, it was resolved that a letter, signed, on behalf of the Council, by the President, Dr. Lush, M.P., should be forwarded to every holder of a Poor-law medical appointment, inviting increased support and co-operation in the effort to ameliorate the condition of the service. This letter has now been issued under the date of December 8th. The main concessions it is hoped to secure are increased emoluments, absolute instead of permissive superannuation, the development of the dispensary system throughout the country, and the payment for sanitary work called for by local boards. The Association has already succeeded in redressing some of the more pressing grievances of Poor-law doctors; it will, we trust, achieve much more in the next Parliamentary session.

The inexactness and perversity of misapprehension of French newspapers when dealing with English manners and names are proverbial. The most astounding blunders are unfailingly made whenever the journalist is exercised on an English subject in which it is necessary to describe persons. The medical press in France cannot be congratulated on a better acquaintance with the proper names of their neighbours. Thus, we find the *Gazette Hebdomadaire* describing the late Dr. J. Hughes Bennett as *M. le Professeur Huebbenet.*

The name of Dr. W. B. Carpenter, Registrar of the University of London, occurs amongst recent recipients of the honour of the Companionship of the Order of the Bath. This somewhat tardy recognition of the high merits and attainments of Dr. Carpenter must be gratifying to the profession of which we have the honour to claim him a member, no less than to a host of scientific friends and admirers in all parts of the world.

We understand that Dr. Ulick Burke has been elected a medical member of the Local Government Board of Ireland, *vice* Mr. Macdonnell, who retires.

REPORT
OF
The Lancet Commission
ON
LUNATIC ASYLUMS.

HANWELL ASYLUM.

THE HOUSE AND ARRANGEMENTS.

The Middlesex County Lunatic Asylum at Hanwell offers a marked contrast to the edifice described in our last report. It is a vast straggling building, in which the characteristics of a prison, a self-advertising charitable institution, and some ambitious piece of Poor-law architecture clamour for precedence. The gates are kept by an official who is attired in a garb as nearly as possible like that of a gaoler. All the male attendants are made to display the same forbidding uniform. Whether the justices of this county are especially proud of their livery it is not for us to determine; but, in the name of common sense and humanity, we must warmly protest against the weakness of parading it perpetually before poor creatures whose only offence is their misfortune, and whose distressing malady should deter governing authorities from obtruding what is, beyond all question, a source of irritation. County asylums are now most unwisely treated as depositories for ex-criminal lunatics, and even prisoners who have become insane before the expiry of their terms of confinement. One of these morbid miscreants in a ward will make the uniform known to the ordinary inmates, and all idea of homeliness is immediately transformed to a depressing sense of imprisonment; while that large class of lunatics who are partly insane and partly vicious instantly take to prison practices, and readily become imbued with the pestilent doctrine of criminal lunacy that, being insane, they may do wrong with perfect impunity. The Committee of Visitors are doing much to improve the conditions of life at Hanwell; it is strange that so startling a mistake as the persistent use of this warder-like uniform has not long ago been remedied. We trust the justices will at once take the matter into their serious consideration. It is one of grave moment regarded from a medical and curative, and not less from an economic, point of view. A suitable uniform might surely be devised which should be sufficiently distinctive and creditable, without adopting the sombre colour and buttoned-up appearance of the conventional prison warder.

Hanwell, as a hospital for poor persons who are neither criminals nor in the ordinary sense of the epithet "paupers," is conspicuously unsuitable. Most praiseworthy efforts have been made by the committee and the medical superintendents to adapt the edifice to its requirements, and much has been accomplished, but more remains to be achieved; and we doubt whether the enterprise is not doomed to disappointment. Practically, the asylum can never be serviceable to use as a *hospital* for any class. It may be available as a place of refuge for imbecile and chronic cases of mental disease in which safe custody is the chief requirement; but the notion of sending there acute or recent, and therefore possibly curable cases, should be wholly and at once abandoned. Speaking generally, the house is five, and the number of inmates three, times as large as the space or community of a hospital for acute mental disease ought ever to be. The immediate and inevitable consequences of this fault are extremely serious. To begin with, it has been deemed necessary to appoint *two* medical superintendents. This division of the medical management has the effect of leaving the ordinary control of the institution to a third authority—the committee and its officers. The result is disastrous. It seems to be forgotten that a hospital for patients affected with mental disease has scarcely anything in common with a hospital for physical disease. In the latter, no doubt, medical and surgical treatment may be separated from the ordinary house management, because the materia medica, therapeutic agents, and methods and appliances of treatment generally, are capable of being separated from such matters as housing, feeding, clothing, and domestic *régime.* But these very matters are *themselves* the drugs and curative agents of the physician who undertakes to treat mental disease. The use of ordinary medicines, which are the principal remedies for disease of the body, are only exceptional and accidental agents in the treatment of disease of the mind. It is by domestic control, by the surroundings of a daily life, by such devices as the colouring of walls, the patterns of floorcloth, the furniture and decoration of rooms, by the influence of pictures, birds, and draperies, the judicious use of different kinds of clothing, suitable occupation and diversions, and, generally, by moulding and controlling the routine life of a lunatic, the psychologist hopes to reach, capture, and re-educate the truant mind, and perhaps re-seat the dethroned intelligent will of his patient. No lay committee can possibly be competent to interfere in these matters. It is essential that there should be only one head to an asylum, and that the whole control of the administration should be gathered up in the *medical* superintendent. Even the authority of a matron, if she be more than a housekeeper, must detract from the personal influence of the medical superintendent with his patients and embarrass his treatment. It would be just as reasonable, or unreasonable, for the lay officials of an ordinary hospital to prescribe the drugs or the instruments with which physicians and surgeons treat physical disease. We think it right to speak strongly on this point, although it is quite possible the medical superintendents at Hanwell may not be prepared to endorse our opinion. The evil apparent in this institution is one of growing magnitude elsewhere, and until justices have the moral courage to place these gigantic institutions on a proper footing, the fact that they are failing in their duty to the insane, and to the ratepayers—because the speedy cure of curable cases is the only true economy — must be brought plainly home to committees and the public. Then, again, it is manifestly impossible the 1700 or 1800 lunatics and imbeciles huddled together in an asylum like Hanwell can be properly cared for. We do not believe there are now cases improperly detained at this asylum, but the evil is quite likely to occur at an institution of such magnitude. Sane individuals may be overlooked in the crowd even by medical officers earnestly and devotedly striving to discharge their public duty. Let anyone calculate for himself how much time a medical superintendent can possibly give to 900 or 1000 patients, the larger number of whom probably stand in need of direct personal and daily assistance. To devise a system of general routine, be it ever so well-ordered, and place a mass of patients under common discipline, is practically to let them take their chance of recovery. This was the highest notion of mental treatment some twenty years ago, but it is not now. As well might the ordinary physician give general directions that all patients suffering from pneumonia should be dosed with tartar emetic, or all the victims of phthisis imbibe large quantities of cod-liver oil. Pulmonary gangrene and hæmoptysis would probably flourish in a hospital so conducted, but it would be idle to pretend that any serious or scientific attempt was made to cure diseases. Mental disease is peculiarly varied in its symptoms and nature, and its victims are remarkable for their idiosyncrasies. Individual knowledge and special treatment are indispensable. Both are impossible in places like Hanwell Asylum. If here and there a case is specially studied and treated, it must be to the neglect of others. A wise and provident Board of Justices will lay these common sense and practical considerations to heart, and carry out the reform to which they point.

Long cold corridors, huge wards, and a general aspect of cheerlessness, are the unavoidable characteristics of a building like Hanwell Asylum—an ungainly multiplication of regulation day-rooms, dormitories, and single rooms, which might be useful as a barrack, but should long ago have been discarded as a residence for the insane. Nevertheless, taking the place as it stands, it is impossible not to be struck with the effort, on the whole much more successful than might have been anticipated, which has been made to render it comfortable. The wards have been improved constructionally wherever it was possible; the walls have been painted, papered, or stincelled; the old stone floors have been replaced with wood; and the stable-like windows have been cut down. All this has been accomplished at great expense and with considerable liberality. Pictures, plants, tasteful ornaments, books, and musical instruments have been provided, and at every turn it is a labour of love to notice the ingenious contrivances for the comfort of the inmates, which have been introduced by the combined intelligence of the superintendents and the spirited humanity of the Committee of Visitors. Nothing can render the asylum a pleasant place to inhabit, or redeem its inherent ugliness. Nothing short of entire reconstruction could make its day-rooms really homely, its dormitories cheerful, or its airing-courts anything but sad and prison-like. Meanwhile what has been done in the way of improvement is very remarkable, and reflects high praise on skilful workmen labouring with defective and unworthy tools.

It is needless to describe the building in detail. Let it suffice to say, briefly, that the house, the arrangements, the general routine of checks and counter-checks, are as complete as those recorded to the credit of Brookwood, with some points to the good. For example, there is an abundant water-supply obtained by sinking an artesian well; the provisions against fire are ample, there are hydrants on all levels, and electric alarm-bells from every ward and officer's room to a common centre; details have been considered down to the placing of a small filter in each dormitory. On the other hand, there is no provision for separating special working communities, which has proved so useful a feature of the arrangements at Brookwood; and the possibilities of isolation in case of epidemic disease, except by some temporary erection, are *nil*. If the Commissioners in Lunacy would concentrate their counsel on points like this, instead of wasting power in recommendations so wonderful as that for "a separate and suitable deadhouse for *each sex*," a real need might be satisfied. As it is, we dread to contemplate what might happen if a serious outbreak of fever or small-pox occurred. There is a recreation hall, but it is much too small, and the system of entertainments is not sufficiently developed. The powerful and most salutary aid of theatrical representations, so well calculated to arrest and interest the wandering mind—perhaps more efficacious than any other instrumentality,—is practically neglected. This is a subject for great regret. The chapel is a vast and gloomy apartment, very like an overgrown meeting-house, which it must be the reverse of comforting to attend. The wise course would be to throw this and the awkward small recreation-hall into one, erect a new and improved stage and dressing-rooms, and build a commodious chapel somewhere in the grounds. At the same time, a block of residences on the cottage principle, here and there, to be used as hospitals for curable cases, or in time of need for infectious diseases, would be worth many hundreds of pounds a year to the county treasurer on the general expenses. We have already spoken of the folly of clothing the attendants in prison uniform. It would be advantageous if the attire of the inmates were more diversified in colour and material, particularly on the female side, where a little pride in dress might obviate the need of special measures to prevent the wilful destruction of clothing. The dietary is good and varied; it includes a liberal supply of vegetables and fish. The daily life of the patients is well ordered, and they appear as contented and quiet as the mistaken policy of associating large bodies of persons with unnaturally excitable temperaments in a ward will allow. The service of the attendants—always a point of the first moment, but extremely difficult to infer from appearances—would seem to be fairly satisfactory. The proportion of attendants is about one to thirteen patients, exclusive of inspectors. The system of night-watching is reported to be good, but it is hard to understand how the large dormitories and multitude of single rooms can be properly supervised. A passage in the latest report of the Medical Superintendent of the Female department bears on this point. "The question of the constant supervision of the epileptic patients by night has engaged my most earnest consideration for some time past, but I have been reluctantly compelled to come to the conclusion that in our present building it would be impossible to attain that object in its entirety; the difficulty arising from the large number of epileptics we have in the asylum—viz. 124; and of them 20, on the average, must sleep in single rooms, on account of their violent and irritable disposition." We must confess to having very little confidence in the check imposed by "telltale" clocks. Those who have had much to do with the insane will agree that it is always more difficult to watch attendants than patients. The weekly cost of inmates is 9*s.* 11*d.* per head. The sewage is utilised, and the farm productive. The drainage is generally good. The warming of a large building like this is of course a work of difficulty: open fireplaces are general and approved. The grounds are not sufficiently planted, and the airing-courts look dismal and bald: many of the seats have no backs. There is plenty of scope for the energy of reform in the provisions for recreation, both in-door and out. Notwithstanding the immensity of the asylum, there is a tendency to overcrowding, and in many of the day-rooms and dormitories both cubic atmosphere and superficial space for exercise are very deficient.

Treatment.

The general principles of treatment adopted at Hanwell are no doubt identical with those in operation at Brookwood, but the practice is in many respects essentially different. It is humane, intelligent, and, in the broad sense, moral and suasive; but it necessarily lacks individuality, and that special character which arises from dealing with a limited number of cases directly. The medical attendants do not approve the use of mechanical restraint, except for surgical purposes; but "seclusion" has been, and still is, an acknowledged remedy at Hanwell, and although it has of late been employed less frequently than in former years, it forms an integral part of the discipline. During the last ten years the records of "seclusion," summarised as completely as we can ascertain the facts, are given in the following table:—

In 1865 there were 96 cases, comprising 193 instances.
„ 1866 „ 72 „ „ 186 „
„ 1867 „ 68 „ „ 116 „
„ 1868 „ 61 „ „ 85 „
„ 1869 „ 36 „ „ 53 „
„ 1870 „ 85 „ „ 159 „
„ 1871 „ 120 „ „ 244 „
„ 1872 „ 48 „ „ 76 „
„ 1873 „ 62 „ „ 127 „
„ 1874 „ 10 „ „ 19 „
558 1258

The above is only an approximation to the actual figures; the returns of seclusion in the female division being deficient for the years 1869 and 1872. It will, however, be seen that the practice is rapidly falling into disuse; and the following remarks, which we reproduce from the Medical Report issued in January of the present year (1875), will show that this is due to change of policy rather than to any supposed variation in the type of disease. Mr. J. Peeke Richards, the medical superintendent of the females, says:—

"Three patients have been secluded on three occasions, two of them being excitable epileptics. ...... During the previous year the seclusions were as follows: 51 patients secluded on 110 occasions. ...... By this it will be seen that the seclusions have materially diminished; and this has been due, I think, in great measure, to further extending the plan that has been adopted here for some time past, and which the large size of our building and the number of our wards freely permit us to do—viz., that of removing the patient, when excited, to some other ward, thus removing her from her real or imaginary grievance or source of irritation; she then, as a rule, soon becomes quiet, and after a few hours returns to her own ward calm and tranquil."

The method thus indicated is in use elsewhere, and with the same beneficial results. Dr. Henry Rayner, medical superintendent of the male division, remarks: — "Five patients have been secluded once, one twice, and one thrice; making a total of seven persons secluded on ten occasions. ...... Six of the patients secluded were epileptics, and the seventh a general paralytic. By the experience of the last year I am strengthened in the opinion expressed in my last year's Report, that seclusion is only very exceptionally a necessity."

The shower-bath is not, we are assured, employed except for ordinary physical purposes; never as discipline. The result of a very careful inquiry into the treatment is to leave the impression that Hanwell has within the last few years emerged from a period of darkness and empiricism and entered an era of scientific progress and enlightenment. The trust to physical remedies is no less diminished than the reliance upon mechanical appliances and methods of restraint. Sedatives and stimulants are going the way of strait-waistcoats and padded rooms. In a word, the treatment is becoming more essentially moral. The difficulties which psychologists doomed to labour in a building like the asylum at Hanwell, and with attendants dressed as prison warders, must encounter and contrive to surmount, can scarcely be over-estimated, and it is only due to the medical superintendents to recognise the conditions under which they labour and the obstacles by which their daily practice is beset. The increased attention to matters of detail, relating to the more intractable and hopeless classes of cases, which recent medical Reports evince, is a satisfactory token of improvement in the general management. The care of "wet" and "dirty" cases is more efficient; the provision of suitable employment for those who can be induced to work—a task of great perplexity—is calling forth better effort, and the result is a larger proportion of patients voluntarily employed—some 60 per cent. in 1874, showing an increase of 10 per cent. on the previous year 1873. Dr. Rayner's class at the Middlesex Hospital visits the asylum for clinical instruction, and while this is a boon of considerable magnitude to the pupils, it beyond question reacts advantageously on the practice of the institution. Hospitals of all descriptions are improved by being used as schools of medicine; and, under proper restrictions—for example, the obvious one of *prohibiting students from entering the wards or showing themselves to the patients except when accompanied by one of the medical superintendents*—the attendance of pupils at an asylum for lunatics is certain to elevate and improve it. The obligations of hospital practice and the emulation of success it implies, must go far to redeem asylums from the character of mere retreats and strongholds for the subjects of madness to drag out hopeless and unhelped lives, and finally die, in.

RESULTS.

The figures in the annexed table are compiled and arranged as were those in the previous report. They speak for themselves. The cases deemed curable—by the medical superintendents for the time being to which the numbers relate—have borne a proportion of 36·76 per cent. to the total of admissions, taking the aggregates of the ten years, not the mean. The mean proportion per cent. of cures to cases "deemed curable," adding the number of such cases remaining at the close of one year to those admitted in the course of the next, has been 53·38. Our reasons for attaching more weight to this calculation than to that which compares the "recoveries" with the "admissions," without regard to the proportion of cases "deemed curable" among the latter, were stated in the last Report. The proportion per cent. of deaths on admission has been 46·27.

* This percentage is upon the total of cases deemed "curable" remaining on Dec. 31st of the previous year (11th col.) and those admitted during the current year (5th col.)

† These totals are the gross of the ten years, not the average.

General paralysis accounts for 433 out of the 1683 deaths, or 25·72 per cent. on the gross total of the ten years. We reserve general deductions until the close of our inquiry. To Mr. J. Peeke Richards and Dr. Henry Rayner, the able superintendents, whose difficulties are great, but whose zeal is apparent, we are indebted for much courtesy and valuable information.

[*Errata in the Report on Brookwood Asylum*, December 4th, 1875.—In the section on "Treatment," ninth line, for "daily dealings with the sane," read "daily dealings with the *in*sane." In last paragraph under same heading, fourth line, for "broodings phantasies" read "brooding phantasies." In the section on "Results," the proportion per cent. of deaths caused by general paralysis upon the total of deaths for the eight years should be 31·04 instead of 31·4.]

DR. RICHARDSON'S LECTURES ON INDUSTRIAL PATHOLOGY.

I.

THE lectures on industrial pathology now being delivered by Dr. Richardson before the Society of Arts are an instance of the anxiety which the Council of that Society feels to advance scientific inquiry on subjects of every-day life, and of practical utility to the masses of the people. In appointing Dr. Richardson to the lectureship, the Council requested him in the present course to take up that part of the subject of industrial pathology relating to those members of the community who belong to the industrial classes proper —to the classes that are engaged in the production of some article of manufacture. The lectures are consequently limited to one class, but incidentally they do, by necessity and by way of comparison, introduce many facts bearing upon other classes of the community. Our contemporary the *Daily News*, which is taking a great interest in this effort, correctly states that the inquiry now in progress is but a preliminary to the greater national inquiry which the Government of this country must undertake, when the *sanitas sanitatum* is in truth more than a party word, spoken but not fulfilled. It is, of course, impossible for any private society to carry out a Government measure, and this is not the attempt that is now being made. At the same time the attempt is not less worthy of regard. It is intended as a means for drawing public attention and interest towards one of the most important of national subjects. It is a means for educating the people so fairly that the demand for official investigation and action shall be irresistible. The plan is eminently practical, and is specially illustrative of the mode of political progress in this country. It has, moreover, an additional advantage of no mean value: it helps to educate professional teachers in the soundest practical knowledge, and thereby to train men of science to take part in the governing body of the nation if their inclinations be in that direction.

In the first or introductory lecture of the course delivered on the 3rd inst., Dr. Richardson first called attention to the previous action of the Council of the Society of Arts in respect to the subject of Industrial Pathology. He drew special attention to an able report and series of questions which had been drawn up twenty years ago by Mr. Simon, F.R.S., Dr. T. King Chambers, and Mr. Twining. Next he dwelt on certain of the detailed reports which had been drawn up by various Governments, naming the Factory Acts Commission, the Children's Employment Commission, the Sanitary Commission, and the great work which has been conducted in the Registrar-General's Office, and in which the labours of Dr. Wm. Farr play so conspicuous a part. The reports of Dr. Headlam Greenhow were also noticed as of signal value. On the whole, the lecturer held that our Governments, with all the faults that had been attributed to them, were deserving of this credit—that they had taken the lead of the Governments of all other countries in the work of sanitary science. Since the year 1802, when factory legislation commenced here, the progress of sanitary science had steadily gone on, until the best system of sanitation with the best results of action was established. In a word, England, the birthplace of true sanitary science, was still the leader. The reading of a quotation from a Belgian publicist on the credit due to England closed this section of the discourse.

Under a second head the lecturer considered the classes of the English community on which it was his duty to treat. Following the Census return of 1871, he defined the six great classes of the English community: — 1. The professional, including the governing class, the army and navy at home, and the representatives of the learned professions, literature, art, and science. 2. The domestic class, including all wives and women of the household, hotel-keepers, inn-keepers, and all who provide entertainments. 3. The commercial class—the buyers, sellers, and lenders. 4. The agricultural class—the tillers of the soil and keepers of the live stock, and of all animals that minister to the wants of man. 5. The industrial class—those who live and work to produce some useful thing. 6. The indefinite class, including (*a*) those who are truly indefinite, who have no fixed home, and no returned and recognisable labour; (*b*) those who are independent, who are *par excellence* "ladies and gentlemen," and (*c*) those who, being under fifteen years of age, are the coming England—the children, scholars, and students of our present generation.

The 22,712,266 persons who made up the whole of the last census were thus divided into classes:—The professional class made up 684,102 of these; the domestic class, 5,905,171; the commercial, 815,424; the agricultural, 1,657,138; the industrial, 5,137,725; and the indefinite non-productive class, 8,512,706. In commenting on these divisions into classes, Dr. Richardson specially dwelt on one singularly curious fact—a fact which shows what a busy beehive this country is — namely, that of the whole 22,712,266 persons who make up the population no more than 168,895 adults are returned as of independent means, and as following no occupation, as, in short, "ladies and gentlemen." The rest are all of some occupation.

Under the third head of the lecture, the 5,137,725 people who constitute the industrial class were considered specially in respect to their diseases and vital condition. It was impossible, the lecturer urged, to study the true industrial pathology of this class until certain disturbing influences, which did not rank strictly as the effects of occupation, were well understood. Five great influences were at work to reduce the life value of the industrial classes, independently of the effects of occupation, and these were: (*a*) intemperance; (*b*) heredity to disease; (*c*) errors of diet, and improper cooking of food; (*d*) moral surroundings; (*e*) uncleanliness.

In illustration of these different disturbing influences, the lecturer adduced a long series of facts. Under the head of intemperance, and the results arising from that cause, he held that, although intemperance is a source of disease and of premature death amongst the industrial classes, it is less destructive to them than it is to some other classes; so that there were occupations, which in all other respects were more favoured, in which the mortality was greater. To prove this position, Dr. Richardson compared two of the unfavourable industrial occupations with that of the publican. The industrial occupations selected were the blacksmith and the engine-driver and railway servant. Taking the mortality of these from the returns of the Registrar-General, and adding to them, in order to make the comparison more complete, the mortality of labourers and of persons of all ages, he showed that the annual death-rate per cent. of the publicans was greater than that of all the rest, at every period of life from above fifteen to seventy-eight years. The facts bearing upon this point were largely illustrated, and are condensed in the following table:—

	Years of Life.						
	15-25	25-35	35-45	45-55	55-65	65-75	75
All Classes	·739	·985	1·305	1·853	3·215	6·076	16·584
Labourers	·513	·872	1·080	1·507	2·734	6·060	18·256
Blacksmiths ...	·366	·918	1·124	1·869	3·225	7·138	19·254
Engine-drivers and Railway servants......	·712	1·121	1·497	2·151	4·059	7·092	20·543
Publicans	·957	1·449	2·044	2·859	4·303	7·465	21·792

It is seen from this table that the men who are engaged in the dispensing of alcoholic drinks, and who are, almost by necessity, led to indulgence in such drinks in small and frequently repeated libations, are from the beginning to the end of their careers specially stricken down with disease, the fruit of their intemperance. These men, in fact, stand in relation to mortality above every one of the industrial classes except one, which is exposed to other dangers of singular import. The lesson taught by the facts requires no comment.

To what extent the same trains of evil extends amongst the industrial classes was not so easily defined, but in its less definite form it was traceable through all the ranks.

The second disturbing cause leading to excess of mortality, irrespective of occupation—viz., inherited disease, was a serious influence, extending specially in those localities of the industrious where the population is densest. Pulmonary consumption is the most marked of these transmitted maladies, but others were named, such as rheumatism, and its concomitants, heart disease and paralysis. Cancer is less prevalent and less distinctly hereditary amongst the industrial than it is amongst the agricultural, the domestic, and the professional classes. A question of immense moment was here considered — whether the transmitted diseases, acquired from the occupation by some of the industrial community, could become hereditary in their offspring independently of the occupation of the offspring?—in other words, whether the original disease once induced by a purely external cause in one person could reappear in the direct line of the family of that person without exposure to the original, or any other similar exciting external, cause? Many difficulties lie in the way of obtaining a correct answer to this question, but Dr. Richardson was of opinion that the balance of testimony lies on the affirmative side.

The third disturbing element, arising from errors of diet and imperfect preparation of food, formed a striking topic in the lecture. As a rule, the industrial classes take too little nitrogenous food, while they often take also an imperfect respiratory sustenance. Absence of fresh food is a great evil, and indulgence (if such a term may be allowed) in tea by the female portion of the class is a serious cause of mischief. The food is not only badly selected as to quantity and quality, but it is so badly cooked that half its value as a sustaining and digestible substance is lost. In some exceptional localities errors of diet of a luxurious kind prevail. In Wolverhampton, during the days of the week which are devoted to "play," the miners feast on all the luxuries of the season. But these exceptions are rare; and, on the whole, one of the greatest reforms required amongst the members of the industrial community is in their diet and in their system of cooking. Peculiarities of body and mind, that are all but racial in their distinctiveness, rest on food and its preparation.

The fourth disturbing element—the moral influences which surround the workman—exert a telling effect on the vital value of the working class. The agricultural labourer may work hard, may fare badly, may be housed shamefully, but he has many advantages. He is engaged out of doors in the fresh air, he has all the beauties of the external nature to delight and refresh him. His work is varied; there is the spring-tide season, with its sheep-washing and shearing; the summer with its haytime; the autumn with its harvest; the other months of ploughing and sowing—constant roundelay of work, with varied change for the mind as well as the body. The artisan has no such pleasures of industry. He passes day by day, month by month, year by year, through the same monotonous labour, until at last his mind recognises but one scene, his hands fall to but one automatic routine. To the end of his career he sees no change, nor chance of being made independent by his skill and his industry. He therefore is naturally apt to become fretful, anxious, irritable; the victim of smouldering passions, which wear out his heart, and lessen his nervous resistance to the many external shocks to which he is daily subjected. Moreover, the limitations of his means lead to limitations in the necessary comforts of his home, and he who is in these straits is rather to be pitied than blamed when, in false measure of the deed, he seeks, ignorantly, still more sorrow in alcoholic indulgence.

The fifth disturbing influence, uncleanliness of person and of attire, was the last dwelt upon. Much of the uncleanliness in industrial work is a part of the industry, and must be accepted as a necessity. But uncleanliness begets the habit of uncleanliness, and so much more is added than need really exist, and it is common to retain the uncleanly condition during hours when work is not being carried on. Dr. Richardson showed the injurious effect of this habit by reference to those who are engaged in working lead, as dippers in the glazing of pottery, and painters. These artisans get into the habit of taking food before they have thoroughly cleansed their hands. They lift some portions of the food—bread for instance—to their mouths with their hands, and in this way they actually swallow the poisonous lead, and become affected, not as is commonly supposed, by absorption of the poison through the skin, but by absorption of it from the stomach.

The last division of the lecture treated upon the actual dangers which spring from various industrial occupations, and which are inseparable from them. It was shown in this part, from the mortality incident to industrial pursuits, that there are causes at work in many of them which, over and above the disturbing influences already quoted, lead to depreciation of vital power and existence. From a table exhibiting the annual rate of mortality in twenty-five well defined callings it was shown, that amongst the industrial callings, the earthenware manufacturers hold the worst place.

As the topics now under consideration opened, it would be discovered that many of the causes operating against industry were irremovable by science in her present condition; that others were removable if science were backed by legislation; that many were easily removable by science without any legislation if those who are most interested in such removal would permit the required improvements. Some advance of opinion among the workers has taken place within the last few years, but it will be long before all opposition to sanitary reform is withdrawn. Dr. Richardson concluded the lecture by quoting one of the "feircely pathetic" passages of the Corn-law Rhymer on this indifference of the industrial worker to the good gifts of science.

HEALTH OF THE NAVY.

The Medical Director-General, true to his word, has this year given to the public his statistical report at a much earlier period than formerly, and we have now before us the particulars on this subject for the past year, which have just been issued. Deputy Inspector-General A. E. Mackay, M.D., who is personally responsible to the Director-General for the compilation of the report, shows a very satisfactory sanitary return as compared with previous years. The total force under consideration numbered 44,530 men, who produced a total of 53,286 cases of disease and injury, which is at the ratio of 1196·6 per 1000, being a reduction compared with the preceding year equal to 3·5 per 1000. A total of 1745 men were invalided, and 422 deaths occurred, this latter number being an increase, compared with the preceding year, equal to 1·1 per 1000, which increase was caused mainly by a fatal outbreak of yellow fever on the south-east coast of North America in May and June of last year.

In summarising the specially interesting features of the Report, it is found that the advantages derived from the operation of the Contagious Diseases Acts continue to be maintained. A table is given in the Report showing the decrease in the ratio of cases of those diseases against which the Acts are more particularly directed, from the year 1864, when they came into operation, to the year 1874, as compared with the ratio of the three years preceding—namely, 1861 to 1863 inclusive. From this table it will be seen that the ratio has been reduced from 104·4 per 1000, the average which obtained from the year 1861 to 1863 inclusive, to 56 per 1000, the average ratio for the years 1866 to 1874 inclusive. In 1874, the ratio of disease was 48·6 per 1000, as compared with 104·4, the average ratio for the three years before the Acts came into force. These statistics need no comment, but may advantageously be commended to the attention of Mr. Stansfeld.

Enteric fever occurred as usual to some extent in the Mediterranean squadron, nearly all the cases originating at Malta. As, however, a general and comprehensive scheme of sewerage for the entire island has been planned, and is about to be carried out, it is very probable, as Dr. Mackay in effect observes, that these works will result in a diminution of this disease among the squadron.

The North American and West Indian squadron has been, comparatively speaking, free from yellow fever during the past year, thus causing a reduction in the death-rate of that station to the extent of no less than 7 per 1000. The fatal outbreak of this disease, however, alluded to above increased the death-rate on the South-east Coast of America station to the extent of 26·1 per 1000, the cases being almost entirely confined to the receiving ship permanently stationed at Rio de Janeiro, thus giving one among many other examples of the unwisdom of keeping vessels at permanent moorings in a tropical climate for any length of time.

The operations on the West Coast of Africa and Cape of Good Hope stations in connexion with the Ashantee campaign were, of course, productive of much invaliding, but nevertheless the ratio of cases entered on the sick-list, as well as the actual mortality, were less than in the previous year. The sanitary condition of the East Indian, China, and Australian stations does not call for special comment. Besides the usual medical and surgical reports from the surgeons of the Royal Dockyards, Naval Hospitals, and Lunatic Asylum, the Report contains Notes and Statistics relating to Boys under Training for the Royal Navy during the past year, by Staff-Surgeon Peter W. Rolston; a Report on the Physical Condition of the Royal Marine Light Infantry, by Surgeon Henry C. Woods, M.D.; some Spectroscopic Observations on certain Pathological Absorption Spectra, by Surgeon E. L. Moss, M.D.; and a most interesting and exhaustive chapter by Staff-Surgeon A. B. Messer, of H.M.S. *Pearl*, on the Physical Geography and Climatology of the Fiji Islands, an abstract of which we must reserve for a separate and prominent notice.

Correspondence.

"Audi alteram partem."

SANITARY WORK IN INDIA.

To the Editor of THE LANCET.

SIR,—Will you kindly afford me space for the following reply to Dr. Macnamara's letter in last week's LANCET on this subject:—

1. Dr. Macnamara has stated his own view that the old high death-rate of the Indian army was mainly due to field service, and doubts the conclusions arrived at by the Royal Commission on the sanitary state of the Indian army after an inquiry extending over several years, and carried on not only in England, but at every station in India, during which there was a concurrence of opinion manifested as to the causes that led the commissioners to adopt the conclusions they arrived at, and of which Dr. Macnamara's own view is not one; and all the sanitary work which has been done in India has followed from the principles laid down by the Commission. On this matter the facts must be left to speak for themselves.

2. Dr. Macnamara's estimate of the sanitary results of sending young fellows to India would, I am afraid, not be sustained by many other authorities, as these very young fellows have been claimed by statistics as among the causes of increased mortality and invaliding; moreover, they supply the chief victims for typhoid fever. Some years ago the matter came before us, in conjunction with the Army Medical Department, and we felt it to be our duty to object to young recruits.

3. Dr. Macnamara appears to place some weight on increased invaliding as a cause of lower death-rates, and cites the experience of 1868 (for Bengal?) with an invaliding rate of 67·7 per 1000, and a death-rate of 21·71 per 1000. The results for all India in 1873 may be compared with Dr. Macnamara's figures. The total invalids were under 40 per 1000, including about 600 men who recovered their health in a month's voyage, and never went to Netley. The actual invalids who went to Netley were under 30 per 1000. The final loss by discharge was 10·3 per 1000, and the total death-rate, including those who died at Netley, for the Indian army, 15·8 per 1000, to which the invalid deaths contributed 5 per 1000, leaving the deaths in India 15·3 per 1000 in that year.

4. In regard to the question of water-supply, Dr. Macnamara appears to consider that the Army Sanitary Commission should have dealt with this subject on the basis of disease poison. But, as I have already pointed out, the Commission, as a purely practical body, is bound not to interfere with doctrine, except to take practical good out of it. Besides, these views are by no means generally adopted in India, and it is scarcely our duty to decide such questions, although we by no means undervalue their teaching. We entirely concur, however, on the Mussack question, and have set our faces against this practice from the beginning. No water, however pure, can be safely carried in skins. At a number of stations metal vessels have been lately substituted. It is true, as Dr. Macnamara states, that several Bengal stations require permanent works, but it is something to have got the Presidency stations improved, and at others there has, I believe, been much good work of a temporary kind done in drainage and water-supply, and at all the conservancy has been undergoing improvement.

5. Dr. Macnamara states that the condition of the civil population of Bengal has not improved, and that in some respects it has degenerated (referring to the fatal Burdwan fever district). Now let us see what the Sanitary Commissioner for Bengal says in his report for 1874. "Very great advancement has been made in the sanitation of municipal towns during the year. The famine has largely extended, in a most practical manner, a knowledge of what is needed and how it can be done"; and he cites reports of improvements from country districts also, in cleansing, draining, filling up holes, improving the water-supply, &c., on a considerable scale. The Burdwan fever has for years been a subject of representation by the Commission with the view to improve the drainage, agriculture, and water-supply, and also the sanitary state of the villages. The difficulties were very great, but a beginning has been made. As a point of experience it may be stated that the same report mentions that in Hooghly district extensive drainage works were completed during the year, "and the result is that a large tract of the country, which was formerly the centre of much disease and mortality, has become healthy." We hope that the same result may be realised, before many years are over, for the whole region.—Your obedient servant,

London, 14th December, 1875. JOHN SUTHERLAND, M.D.

UPPINGHAM SCHOOL.

To the Editor of THE LANCET.

SIR,—I understand that the Rural Sanitary Authority at Uppingham has sent you a resolution about the school. I should be obliged if you will publish at the same time with it, or in your next issue, if it has already appeared, the letter from Mr. Robert Rawlinson, who has been appointed by the Government Board at Whitehall to decide on the whole question. Mr. Rawlinson wrote this letter on having the resolution from Uppingham put before him. I enclose a copy. Believe me, yours faithfully,

EDWARD THRING.

The School House, Uppingham, Dec. 10th, 1875.

"UPPINGHAM SCHOOL.

"Local Government Board, Whitehall,
"December 9th, 1875.

"DEAR SIR,—I have not yet seen the plans, reports, and estimates of Messrs. Rogers Field on behalf of the Rural Sanitary Authority, and of Mr. Tarbotton on behalf of the school's trustees, and until I see these, and report, it is premature to publish any statement relative either to the state of the town or the state of the school.

"I am yours truly,

"The Rev. Edward Thring." "ROBERT RAWLINSON.

⁂ We insert the above letters at the request of the Rev. Ed. Thring, the Head Master of Uppingham. The resolution referred to appeared in our columns last week: it was to discountenance a premature return of the scholars till the Sanitary Authority at Uppingham were able to report that "each individual house in connexion with the school is in a perfect sanitary condition." We do not see that these letters in any way affect the resolution in question, which seems to us, under the circumstances, both reasonable and prudent.—ED. L.

Medical News.

Royal College of Surgeons of England. — The following gentlemen, having passed the required examination, were admitted Licentiates in Midwifery at a meeting of the Board of Examiners on the 15th inst. :—

Benton, Samuel, M.R.C.S., Wakering Hall, Essex.
Blake, Andrew H., M.R.C.S., Drury-lane.
Burgess, Edward John, M.R.C.S., Brentwood, Essex.
Hosford, Thomas Stroud, M.R.C.S. Mornington-road.
Jevers, Eyre, M.D., Tonbridge, Kent.
Pickburn, Thomas John, M.D., Sydney, New South Wales.

It is stated that nearly 350 candidates have entered their names for examination in general knowledge for the Membership and Fellowship of the Royal College of Surgeons, a number quite equal to that of any previous year. The examination will commence on Tuesday next (Dec. 21st) at the University of London (Burlington-gardens).

Apothecaries' Hall. — The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on Dec. 9th :—

Bickford, William, Ashburton, Devon.
Carey, John Thomas, Trinity-square.
Cross, Philip Henry Eustace, Lancaster-road, Notting-hill.
Henbeck, Fredk. Emanuel, Westbourne-terrace North.

The following gentlemen passed the Primary Professional Examination on the same day :—

Henry Thomas Batchelor and Robert Godfrey White, London Hospital; John Walter Stamp, Queen's Hospital, Birmingham; Joseph Henry Marsh, St. Thomas's Hospital; Alfred Moxon Turner and Walter Henry Lawrence Welchman, Guy's Hospital.

Valentine Stone, Esq., F.R.C.S. Edin., has been appointed a Justice of the Peace for the county of Kincardine.

British Medical Defence Association.—At a general meeting of the members of the British Medical Defence Association, held on the 10th inst., Dr. B. W. Richardson was elected president for the ensuing year, Dr. Alfred Meadows and Mr. James R. Lane, F.R.C.S., were elected vice-presidents, and Mr. George Brown was elected honorary secretary. An adjourned meeting is to be held on Tuesday afternoon next at the Guildhall Tavern, Gresham-street, to elect the council and remaining officers of the association.

London Hospital Medical Society's Soiree.—The soirée of the London Hospital Medical Society was held in the Medical College on Friday, the 10th inst. By the kind permission of the council the greater part of the ground floor was in use. The Anatomical, Pathological, and Materia Medica Museums, which were used as a promenade, had numerous curiosities and objects of interest displayed in them. The Reading-room was devoted to microscopes, stereoscopes, and photographic views. In the Anatomical Theatre a good selection of glees and solos were admirably performed during the evening, and some recitations given with great success. A large number of lime-light views were shown in the Chemical Theatre, thanks to the kindness of Dr. Tidy, who placed the necessary instruments at the disposal of the committee. Refreshments were provided in the lecturers' room. The rooms were crowded, many strangers and neighbouring medical men being present, together with a large number of the members of the society, and all seemed much pleased and interested by the entertoinment, which lasted from seven o'clock to half-past ten, and the only cloud upon which was the serious indisposition, and consequent absence, of the President, Mr. Mercier.

Medical Appointments.

Baird, Mr. J., has been appointed a Midwifery Assistant at the Steevens's Hospital, Dublin.

Barnard, Mr. W. W., has been appointed a Midwifery Assistant at the Steevens's Hospital, Dublin.

Bookless, J. P., M.D., L.R.C.P.Ed., has been appointed a Physician to the Kelso Dispensary.

Browne, J. C., M.D., has been appointed a Chancery Visitor of Lunatics, vice Bucknill, resigned.

Clarke, H., L.R.C.P.L., M.R.C.S.E., has been appointed Resident Medical Officer to the West Riding of Yorkshire Prison, Wakefield, vice Wood, resigned.

Cross, F. R., M.R.C.S.E., has been appointed Medical Tutor and Sub-Dean at King's College, London, vice Philpot, resigned.

Devany, P. C., L.R.C.P.Ed., L.R.C.S.I., has been appointed Medical Officer to the Sligo Model School, and Certifying Factory Surgeon for Sligo, vice Tucker, deceased.

Donovan, Dr. J. I., has been appointed Medical Officer to the Royal Gunpowder Mills, Ballincollig, and to the Royal Irish Constabulary, vice Rountree, deceased.

Eminson, R., M.R.C.S.E., has been reappointed Medical Officer of Health for the Gainsborough Rural Sanitary District: £125 for one year.

Etheredge, G. F. E., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer to the Bromyard Union Workhouse for twelve months, vice Powell, whose appointment has expired.

Forbes, Dr. L., has been appointed Resident Obstetric Assistant to the Westminster Hospital, vice Davies, resigned.

Gibson, C., L.R.C.P.Ed., L.R.C.S.Ed., L.M., has been appointed House-Surgeon to the Bootle Borough Hospital.

Harvey, H. F., M.R.C.S.E., has been appointed Registrar to the London Fever Hospital.

Heap, C. S., L.K.Q.C.P.I., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Burnham District of the Eton Union, vice Masterman, resigned.

Johnson, J. J., L.R.C.P.L., M.R.C.S.E., has been appointed House-Physician to the Midland Counties Supplementary Hospital for Chronic and Incurable Diseases, Leamington.

Keetley, C. R. B., L.R.C.P.L., M.R.C.S.E., has been appointed Assistant Demonstrator of Anatomy at St. Bartholomew's Hospital Medical College.

Lowne, B. T., F.R.C.S.E., has been appointed Ophthalmic Surgeon to the Great Northern Hospital, vice Vernon, resigned.

Lucas, T., M.R.C.S.E., has been appointed Medical Officer to the Cambridge Police Force, vice Hough, resigned.

Mackintosh, A., M.D., L.F.P. & S. Glas., L.M., has been reappointed Medical Officer of Health for the Whittington Urban Sanitary District for twelve months from the 15th of April, 1876.

Maples, R., M.R.C.S.E., L.R.C.P.Ed., has been appointed a House-Surgeon to St. Thomas's Hospital.

Newby, C. H., M.R.C.S.E, L.R.C.P.L., has been appointed a House-Surgeon to St. Thomas's Hospital.

Nicholson, W., M.D., C.M., has been appointed Medical Officer for the Greenwich Central District of the Greenwich Union, vice Wade, resigned.

Norman, J. C., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Needham Market West District of the Bosmere and Claydon Union, Suffolk, vice Beck, resigned.

Potter, H. P., M.R.C.S.E., has been appointed House-Physician to St. Thomas's Hospital.

Rossiter, G. F., M.R.C.S.E., has been appointed Resident Accoucheur to St. Thomas's Hospital.

Sampson, H. M., L.R.C.P.Ed., M.R.C.S.E., has been appointed Resident Medical Officer to the Gloucester Infirmary, vice Morris, resigned.

Smith, J., M.B., C.M., has been appointed Medical Officer for No. 7 District of the Newport Pagnell Union, vice Heygate, deceased.

Turnbull, G. H., M.D., L.R.C.S.Ed., has been appointed a Physician to the Kelso Dispensary.

Wallis, F. M., M.R.C.S.E., has been appointed Medical Officer for the No. 4a District of the Hailsham Union, Sussex.

Births, Marriages, and Deaths.

BIRTHS.

Bate.—On the 2nd inst., at Bethnal-green-road, the wife of Geo. Paddock Bate, F.R.C.S.Ed., of a son.

Cunningham.—On the 9th inst., at Woolwich, the wife of J. P. Cunningham, M.D., Surgeon-Major Army Medical Department, of a son.

Hogg.—On the 8th inst., at Gunnersbury, Chiswick, the wife of Wm. B. G. Hogg, M.D., of a son.

Peacock.—On the 11th inst., at Albion House, Gloucester, the wife of H. Peacock, M.R.C.P.L., of a son.

Stephen.—On the 12th inst., at Queen's-gate-terrace, the wife of Andrew Stephen, M.D., of a son.

Woodman.—On the 8th inst., at Prospect-terrace, Ramsgate, the wife of Samuel Woodman, F.R.C.S.E., prematurely, of a son, still-born.

MARRIAGES.

Gandy—Worsley.—On the 9th inst., at St. John's, Hackney, Wm. Gandy, M.R.C.S.E., of Parkstone House, Gipsy-hill (late of the P. & O. Co.'s Service), to Julia Matilda, youngest daughter of the late Charles Worsley, Esq., of Upper Clapton.—No Cards.

M'Intyre—Stiven.—On the 9th inst., at St. Stephen's, Westbourne-park, Andrew James M'Intyre, M.B., to Mary E. M., daughter of the late W. S. Stiven, M.D.

Smith—Gardiner.—On the 8th inst., at St. George's, Hanover-square, Ernest Louis Tyler Smith, M.B., to Rose Eliza Catherine, daughter of Wm. Gardiner, Esq.

DEATHS.

Alderton.—On the 4th inst., at Heigham, Thos. Alderton, M.R.C.S.E., late of Reepham, aged 54.

Clark.—On the 10th inst., at Cecil-street, Strand, H. Clark, M.R.C.S.E., late of Southampton.

Cremen.—On the 6th inst., at Millbank-street, David Cremen, M.B., aged 47.

Desmond.—On the 10th inst., at Irvine-street, Edge-hill, Liverpool, L. E. Desmond, M.D., aged 56.

Graham.—On the 2nd inst., at Stockport, G. Y. Graham, M.R.C.S.E., aged 70.

Hassall.—On the 13th inst., at St. George's-square, R. Hassall, M.D., late of Richmond, Surrey.

Morison.—On the 9th inst., at Horton-green, Bradford, Yorkshire Andrew Morison, Surgeon R.N., seniority Nov. 12th, 1813, aged 89.

Ridlington.—On the 5th inst., at Ramsey, Huntingdonshire, Hicks Ridlington, M.R.C.S.E., aged 73.

[N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*]

Notes, Short Comments, and Answers to Correspondents.

WANT OF HOSPITAL ACCOMMODATION FOR INFECTIOUS DISEASES AT SHEFFIELD.

ALTHOUGH the general death-rate in Sheffield has recently been low, the borough has been suffering for some weeks from the prevalence of fever of a severe type, and the resources of the workhouse have been greatly taxed by the necessity for admitting cases which, strictly speaking, are not proper cases at all. This town, however, unlike most other large English towns, possesses neither a fever hospital nor any other hospital accommodation for the treatment of non-pauper cases of infectious diseases. A recent case, in which, after an accidental delay in obtaining an order from the relieving officer, a patient was admitted to the workhouse in a state of delirium from typhus fever, and died shortly after, was the subject of an inquest, at which the guardians were blamed by the jury for what appears to have been a purely accidental delay in the admission of the sufferer. The fact is, the man was very far removed from a pauper, and his friends naturally were averse to sending him to the workhouse until delirium made him unmanageable. It appears to us that the real blame rests with the Town Council, which, as the sanitary authority of the borough, has neglected to provide a borough hospital for the treatment of non-pauper cases of infectious diseases ever since sanitary authorities were empowered to establish such hospitals by the Public Health Act of 1872. Dr. Griffiths, the medical officer of health, has in each of his last two Annual Reports dwelt on the danger to the community arising from the want of this hospital accommodation. In small towns there is some excuse for objection to incur the expense of such hospital accommodation; but in a prosperous community like Sheffield such neglect or parsimony is little short of a disgrace to the town. We may also take this opportunity of saying that no report has yet reached us of any intention on the part of the medical officer of health or the Town Council of putting in force in Sheffield the provisions of the Artisans' Dwellings Act of last session.

Mr. T. Laffan.—The Act referred to applies only to England and Wales.

TREATMENT OF SHOULDER PRESENTATIONS.

To the Editor of THE LANCET.

SIR,—I have just received a letter from Dr. P. R. Maxson, of Syracuse, New York, giving an account of his "treatment of shoulder presentations," and, as it is a matter of general interest to the profession, I have concluded to send it to you for publication.

He says: "I hasten to give you in a condensed form an account of my plan of *treating shoulder presentations.* Gravity is the principle invoked; and I was led to the discovery in 1860 by placing a woman with prolapsed cord on her knees, with her head and shoulders low, as recommended by Dr. T. G. Thomas, of New York, in order to effect its reduction, and finding that while she was in this position an abnormal (abdominal) presentation was spontaneously converted into a normal one. Having reflected on this circumstance, I was induced a few weeks later, when called in consultation in a bad shoulder presentation, to try *position* as a means of rectifying it. I was very anxious in regard to the case, because the lady had lost three children already from 'turning to deliver' in shoulder presentations. Her regular attendant, Dr. G. N. Dox, of Geneva, New York, a physician of attainment and experience, happened to be the *confrère* in whose practice the case of prolapsed cord, above referred to, had occurred; and, instead of 'turning' himself, as had been so unsuccessfully attempted in the lady's previous labours, he sent for me in consultation. Remembering the fate of the other children, and finding this one very large, I suggested the feasibility of correcting this *shoulder presentation* in the same manner as I had corrected the *abdominal* in the first instance. With his consent I made the effort in the following manner:—I folded several quilts compactly, laying them one upon another to the height of about one foot, and assisted her to kneel upon the quilts, with her head and shoulders resting upon the bed, and her face forwards, so as to bring her body to an angle with the bed of nearly 90 degrees. I then pressed my hand gently against the shoulder, which readily receded, until I was enabled to clasp the vertex with my fingers, and with the assistance of the next pain to so 'engage' it, that, when the patient was placed upon her left side and the quilts removed, a perfectly natural presentation presented itself. In a few hours the labour terminated in the delivery of a healthy boy, weighing ten pounds. Only a few moments were occupied in the process, and subsequent experience convinces me that *shoulder presentations* can generally be converted in this way into *natural* ones, without a resort to 'turning,' and with no risk for the mother or the child."

I would add that this method of treatment has received much attention in America, and that no inconsiderable amount of testimony has been accumulated in support of its efficacy. Dr. Maxson also informs me that he submitted his views in this regard some years since to Sir James Simpson, and that they were cordially endorsed by that distinguished gentleman.

Yours respectfully,
Rue Caumartin, Paris, Dec. 9th, 1875. EDWARD WARREN, M.D.

BRITISH QUALIFICATIONS IN CANADA.

EVERY colonial Legislature has the power to enforce medical registration within its jurisdiction. It can require those who have been registered in Great Britain to be registered again in the colony; provided, however, that any person who has been duly registered under the Medical Act shall be entitled to be registered in any colony upon payment of the fees (if any) required for such registration, and upon proof of his registration under the said Act.

F.R.C.S. (Ireland) has omitted to enclose his card.

FEMALE QUACKS AT MISSION HALLS.

SOME time ago we pointed out the sanitary evils resulting from mistaken zeal on the part of the promoters of "missions" who regarded a little hot-bed of pestilence and poverty as their preserve. We contended that the philanthropy of these people was obstructive and mischievous, and we appealed to the common sense of the public to set aside its influence and press forward in the path of uncompromising sanitary reform. We regret that it should be necessary to take up the cudgels against an equally irrational and no less pernicious practice. It seems that the "missionaries" have taken to quackery as a new vagary. Certain lady "philanthropists" indulge the passion for meddlesome notoriety by prescribing for the poor victims of their benevolence. We cannot but deplore the feebleness of a verdict which failed to carry the charge of manslaughter home to these female triflers in the practice of medicine. The proceedings of the coroner's inquest seem to have been treated with contempt by the promoters of the Mission Hall. The medical evidence laid before the coroner showed that a case of bronchitis had been grossly misconducted and practically left without help. We fear the "surprise" expressed by the jury will not occasion the ladies of this interesting mission any great discomfort. Something more than implied censure and covert rebuke is needed to repress the pretentiousness of zeal without knowledge.

An Ulster Boy should consult a medical man.

ANIMAL VACCINATION.

To the Editor of THE LANCET.

SIR,—The letter on this subject in your issue of the 4th inst., as also the notice taken by the Medical Society of London, induce me once again to urge upon the profession, and, through them, on the Government, the importance of establishing institutions in Great Britain where heifer lymph can be obtained. When working at this subject in 1869, I visited Dr. Blanc's establishment in London, M. Lanoux's in Paris, and the large national institutions in St. Petersburg and Brussels, in all of which I spent much time carefully examining the whole bearings of the question. The impression I thus received was so much in favour of animal vaccination (i. e., the vaccination of children with lymph never before in contact with human blood, but which, removed from the cow as the original vaccine, has been transmitted through heifers in successive series *without intermission*) that I published my views on the subject in the *British and Foreign Medico-Chirurgical Review*, April, 1870, and also brought the matter before the British Medical Association and other Medical Societies. Since that date my experience impresses me daily more and more in favour of heifer lymph. I would not urge on our Government the establishment of institutions for the vaccination of calves, and the distribution of lymph from this source, if I regarded such merely as toys or sops to semi-ignorant and well-meaning agitators; but, after bestowing very great care in sifting the question, I feel sure we have no reliable data for stating *positively* that the transmission of vaccine through innumerable human subjects does not modify—that is, cause deterioration in the protective qualities of—vaccine, and the experience of every variolous epidemic furnishes a considerable amount of proof in favour of this supposition. I do not believe in the transmission of disease by vaccine lymph; but it has always appeared to me illogical and unphysiological to insist on the exceptional character of vaccine lymph in this respect. Any other organic fluid transmitted through innumerable animals would be regarded as modified by the process; yet, because vaccine vesicles in the 300th generation from the cow *appear* what is termed normal or Jennerian, it is concluded that the fluid they supply has been unaltered by such transmission. During the last few years I have vaccinated scores of heifers, and likewise scores of children from them, and I never expect nor find either to fail. I am as sure when vaccinating the heifer as when vaccinating the child by the arm-to-arm method of obtaining a full or nearly full complement of vesicles. During the prevalence of the last variolous epidemic in Liverpool I found the advantage of being able to vaccinate heifers, as when the supply of vaccine ran short I was able to supply my colleagues with plenty more in a few days. This employment of retro-vaccine lymph from the heifer I have tried for some years, and found most successful. The proposal I brought forward before the British Medical Association in 1869, and which I would still urge, is the establishment in four great centres (as London, Liverpool, Edinburgh, and Dublin) of the means for maintaining a sufficient succession of vaccinated heifers to afford a constant supply of this lymph. By making a moderate charge to those availing themselves of these establishments, these institutions would be made in a few years self-supporting. Moreover, such institutions need not disturb nor interfere with the existing public vaccination stations; but they would greatly increase the confidence of the public in vaccination by affording the alternative. The cost of maintaining each station would be about £200, exclusive of the vaccinator's salary. The only difficulty I have met with has been in the forwarding of such lymph to distant parts, as India or Africa. On ivory points heifer lymph will remain active almost certainly for ten days, often longer; and, if circumstances required it, no doubt here, as in France and Russia, a special form of capillary glass tube could be produced, which would enable the lymph to be preserved much longer. I have obtained heifer lymph from St. Petersburg a month after its removal from the heifer, and it was still active.

I hope you will excuse me occupying so much space in THE LANCET, but believe that I do so through a feeling of the very great importance of the subject. I am, Sir, yours faithfully,
Birkenhead, Dec. 7th, 1875. P. M. BRAIDWOOD.

AS USUAL.

SPEAKING of the recent appalling explosion in the mine of the Swaithe Maine Colliery, the *Newcastle Daily Chronicle* reporter remarks:—"Not the least pleasant feature of a day literally crowded with horrors, either for those who descended the pit or those who congregated about the shafts, was the patient and considerate manner in which several doctors waited to give their services should such assistance be needed by the exploring parties."

Mr. Macauliffe.—We fear there is no redress.

SEQUESTRATION OF RATES FOR NON-ABATEMENT OF A SEWAGE NUISANCE.

VICE-CHANCELLOR SIR JAMES BACON, on the 9th inst., ordered two writs of sequestration to be issued for non-compliance with orders of the Court for the abatement of sewage nuisances, although he ruled that in each case the writ should not be put in force until the expiration of three months, in order to give time for the execution of the works. The first case was against the Commissioners of the Improvement District of Harrogate, for evading an injunction which forbade them to foul the out-beck with the town sewage, by pouring the sewage upon some land acquired for the purpose, from which it still found its way into the beck, in the condition of which there was no improvement. The Vice-Chancellor, in ordering that the writ of sequestration should issue, made some strong but wholesome remarks upon the evident neglect of the Commissioners. A similar application was in the second case made by the Attorney-General against the Corporation of Newcastle-upon-Tyne with reference to an injunction granted so long ago as 1861, since which the Corporation have adopted the process of defecation in subsidence tanks. The Vice-Chancellor was convinced in this case also that neglect on the part of the Corporation was proved, and granted the writ of sequestration applied for. Whereas it is very satisfactory to find that local authorities are not to be allowed lightly to disregard orders of the Court with respect to the abatement of sewage nuisances, it is impossible to avoid some sympathy with the defaulting authorities on account of the all but insuperable difficulties which in so many places stand in the way of sewage disposal without creating a nuisance.

CHLORAL HYDRATE AS A HYPNOTIC.

To the Editor of THE LANCET.

SIR,—In reply to your correspondent, "F.R.C.P.," who wishes to know what effects the prolonged administration of chloral hydrate has on the system, and whether it ever gives rise to gastro-enteritis, I beg to state that there are several patients in this asylum who have been taking chloral hydrate continuously—i. e., every night—for periods varying from six months to two years, and in no instance has its prolonged use been followed or accompanied by gastro-enteritis, vomiting, failure of appetite, or any symptom indicative of mischief. I generally give thirty grains for a dose, rarely more than forty grains, and in the vast majority of cases I find that it answers the purpose required—viz., to give sleep to excited and restless patients. Occasionally with a fresh patient who is considerably excited, the ordinary dose (thirty grains) does not act; but I attribute that more to the insufficiency of the dose than to the uncertainty of the medicine, as I almost invariably find that the dose of forty grains has the desired effect of procuring sleep. There is a patient here who has taken chloral regularly for over two years, and who could not do without it, and who has fair health and appetite, and no symptoms whatever of gastro-intestinal irritation. I have seen a few, though very few, patients in whom chloral produced slight headache and furred tongue, though in a much less degree than opium generally produces. Chloral hydrate is used largely and daily in this asylum, and in no single instance have I noticed alarming or dangerous symptoms in connexion with its administration. I regard it as a safe and valuable hypnotic in all cases of sleeplessness, and especially so in the excitement of acute mania.

As to whether the prolonged use of chloral hydrate produces change of disposition or perversion of the moral feelings I am unable to say, as my experience in its use has been principally amongst the insane.

I am, Sir, yours respectfully,
J. G. THORNLEY, M.D.,
Assistant Medical Officer.
Leicestershire and Rutland Lunatic Asylum, Dec. 1875.

To the Editor of THE LANCET.

SIR,—In reply to "F.R.C.P." in your last issue, I beg to inform him that I had in 1870 a female patient, who took, after a severe confinement, on several days six drachms of chloral hydrate, and on one day nine drachms (540 grains), with decided perversion of morals. It also produced a tendency to suicide—in fact, anything but sleep,—and had to be abandoned, as its good services passed off after the first few thirty-grain doses.

Yours truly,
West-Green-road, Tottenham, Dec. 8th, 1875. JAMES BUNTING.

X. Y. Z.—Dr. Fenwick's little Manual of Diagnosis, published by Churchill, would probably meet our correspondent's requirements.

THE GOODCHILD FUND.

THE following further subscriptions in aid of the widow and children of the late W. H. Goodchild have been received:—

John Adams, Esq.	£0	10	0	Dr. Andrew	£5	5	0
Alban Doran, Esq.	1	1	0	Dr. Clement Godson	1	1	0
The Misses Ellery	1	1	0	W. S. Savory, Esq.	1	1	0
Cornelius Hanbury, Esq....	1	1	0	Dr. Andrew Brown	1	1	0
Alfred Willett, Esq.	2	2	0	Jabez Gravell, Esq.	3	5	4

6, Bedford-place, Dec. 14th, 1875. F. DE HAVILLAND HALL, M.D.

Medicus.—A great many of the cases are recorded in his book, especially the second edition.

"TAPEWORMS": CORRECTION No. 2.

To the Editor of THE LANCET.

SIR,—Dr. Edwards Crisp, in correcting the notes by your reporter of the discussion on my paper on "Tapeworm," recently read to the Medical Society of London (THE LANCET, Dec. 4th, p. 803), has stated that I said "that they (tapeworms) sometimes were" introduced by eating vegetables. I never said so. What I said was that I had an idea or supposition that they might be like the germs of other parasites. I did not enter into my reasons for this idea; for the object of my paper was purely practical, and relating to treatment principally. My friend Dr. Crisp has mistaken me, and I think it right to correct the mistake.

Yours faithfully,
Euston-road, Dec. 13th, 1875. JOHN BRUNTON.

Dr. J. Birkbeck Nevins, (Liverpool.)—Our information was derived from the newspaper report of the meeting. We are unable to afford the space for our correspondent's lengthy communication. The controversy in which he has been engaged in a contemporary has already been sufficiently extended.

A Subscriber.—Appointments as surgeons to emigrants are obtained from the owners of vessels chartered for emigration purposes. Emigrant surgeons must in all cases be registered medical practitioners.

CASE OF HÆMORRHAGE AND PERITONITIS AFTER EATING CHEESE: DEATH WITHIN FOURTEEN HOURS.

To the Editor of THE LANCET.

SIR,—The following case, as illustrating the fatal effect of over-ingestion of cheese, may have an appropriate significance at the present season, when plum-pudding is in process of gestation, and the fatted ox is under sentence of execution.

About 6.30 A.M. on the 6th of this month I was called to attend M. C——, aged twenty-nine years, a moderately stout woman, married two years, no children. I found her in bed, suffering from intense pain in the abdomen, round the umbilicus. The pain was not increased by steady pressure, but pressure with the points of the fingers aggravated it. The abdomen was like a drum, hard and tympanitic all over, save in the umbilical and hypogastric regions, which were dull on percussion. She stated she was not pregnant, and had menstruated three weeks ago. Pulse slow; hands chilly; countenance sallow; tongue whitish in the centre; skin cool; intellect clear. Being questioned as to what she had last eaten, she said she had eaten some cheese to supper on Sunday night. She had been at church on the 5th, a cold, frosty day, and was apparently quite well then. Early on Monday morning she first experienced pain in the belly, with a feeling of chilliness. The pain gradually increased, and became so excruciating that she called out frequently. Her sufferings induced her friends to try their own remedies before sending for medical aid. Brandy, Cayenne pepper and other condiments were freely administered without any relief, as well as a mustard poultice applied to the abdomen, followed by wet cloths to the site of the pain, which seemed to have no other effect than wetting the patient's linen, and keeping her body in a state of cold damp. This was the treatment pursued before I saw her, and the state of the patient was by no means cheering. The pain had never intermitted from its commencement, though there were slight remissions of it. Vomiting had occurred once, but the precise nature of the vomit could not be ascertained. No cheese was, however, to be seen in it. I then gave her thirty drops of chlorodyne, applied hot flannels to the abdomen, and remained with her for half an hour, during which time she did not vomit. At 8 A.M., being nothing better, I prescribed compound colocynth pill, with one grain of extract of belladonna.—10 A.M.: Her husband called, and asked me to see her again, as she appeared to be worse. She was then doubled up in bed, fixed, as it were, by the pain, and said she felt her bowels in a lump. On examination, a distinct tumour round the umbilicus could be felt, giving one the same impression as that of the uterus when contracted after expulsion of placenta, only its contour was more undefined, and its surface more irregular. Pulse nearly imperceptible; pallor of the lips; hands icy cold. I gave her a hypodermic injection of morphia, one-quarter of a grain. She felt slightly better after this, the pain shifting and becoming more diffuse; the pulse also was easier felt, though small and thready. Having to go away to see another patient at some distance, I ordered a dessertspoonful of wine to be given in my absence, and directed that she was on no account to be left alone or unattended.—12 noon: Her attendant informed me that she had slept for about twenty minutes, had taken some wine, and vomited a quantity of cheese in pieces of about half an inch square. I then administered a mustard emetic, the pain being still very severe, though the sense of it was evidently less. She vomited the greater part of the emetic, and fell back in a faint, but rallied for a few seconds; then fainted again, this time fatally, notwithstanding brandy was given, hot bottles applied to the præcordium, and artificial respiration performed for about half an hour.

The post-mortem examination was made twenty-four hours after death by Dr. MacKenzie and myself. Rigor mortis well marked. A layer of fat, three-quarters of an inch in thickness, was cut through before reaching the linea alba. On opening the abdomen, blood escaped, and was found occupying the general peritoneal cavity. The greater part of the small intestine was of a deep claret colour. The mesentery was deeply congested, the redness being arborescent; its vessels felt varicose to the touch, and had a beaded appearance. Near the termination of the ileum was a twist of the intestine upon its own axis. The portion of intestine below this constriction was of less diameter than that above it, and as congested; but as the twist could be uncoiled, and fluid apparently forced through it, it was doubtful whether it was of ante- or post-mortem occurrence. No perforation of bowel could be discovered; but on making an artificial opening, a considerable quantity of dark fluid blood was found occupying the intestine. The stomach, liver, and colon were if a pale colour; but these viscera were not disturbed from their natural attachments. Further examination being deemed unnecessary, in deference to the wishes of the relatives, who were reluctant to grant a post-mortem, and only on condition that it should be limited to the discovery of the cause of death.

Remarks.—This was evidently a case of perforation and hæmorrhage from the bowel, induced by a fit of gluttony. That the cheese the woman ate ably assisted by its mechanical irritation in destroying life by asthenia is evident, having passed undigested from the stomach into the small bowel, and there given rise to all the morbid phenomena. That it was harmless in itself is proved by the husband of the deceased woman having eaten of the same cheese at the same time, and by his having experienced no bad effects from it. Vomiting was not at all a prominent or an early symptom, as she retained medicine and a drink of gruel. No symptom of gastritis or irritant poisoning existed. An interesting feature in the case is that of the hæmorrhage obscuring many of the symptoms, acting like a hungry leech on the general circulation, and combining with the extreme pain to stop the heart's action. The time had also arrived for the reappearance of the catamenia. Could it be that the presence of the irritant cheese determined the afflux of blood from the uterus to the intestine, and there set up fatal inflammation, the focus of the latter being some latent ulceration of which there was no history during life? The weather was also extremely cold and frosty. Whatever hypothesis is correct, the corollary is plain, that over-ingestion of food may prove as fatal as over-indulgence in drink.

I remain, Sir, yours truly,
Strone, near Greenock, Dec. 1875. R. G. M'CALMAN, M.D., C.M.

On the Relation of Syphilis to Aneurism.

To the Editor of The Lancet.

Sir,—The presence in your impression of the 4th inst. of a leading article on my paper "On Aortic Aneurism in the Army, and the conditions associated with it," leads me to ask for space in your columns in reply to your objections to my deductions.

And, first, I would wish, while generally acknowledging your accurate and full report of the comments passed upon it at the meeting, to supply an important omission—in fact, the only remarks tending in any way to corroborate my deductions. I refer to the observations of the President, Sir J. Paget, who (if I heard his words aright) said that not only was there a growing opinion among surgeons on a connexion between aneurism and syphilis, but also that, in his opinion, speaking as a surgeon, if the subclavian, iliac, femoral, and popliteal aneurisms in young subjects were carefully inquired into, the proportion with syphilis would be found to be equal to that stated in my paper as occurring among the aortic aneurisms in the army. The value of this, coming from such a source, I need not dilate upon. I would also here take the opportunity, in order not to mislead the reader of my paper, to correct the word "saturated" as it occurs in the sentence "saturated with syphilis," better substituted by "undoubtedly infected"; for my object, both in the paper itself and also in my reply, was not to overstate, but to convey the impression that 50 per cent. of the aneurismal cases, either during life or after death, illustrated more or less of lesions (which I detailed) acknowledged specific.

The relation of syphilis to aneurism as a direct cause leading to a distinct change in the inner coat of the aorta.—I need not travel over again the remarks in my paper supporting such a deduction. Suffice it to say that the change in the walls of the vessel is an unquestionable tissue growth, and as such there must be an agency to originate and support it. That this agency is in a certain number of cases syphilis, I consider substantiated by the statistics brought forward by me in the aneurismal, syphilitic, and non-syphilitic cases, as well as by the nature of the growth itself—not to be distinguished in its ultimate elements and phases from the growth, acknowledged specific, occurring on the bones; but whether possible of differentiation from that associated with rheumatism and alcoholism cannot at present be decided beyond doubt. In the opinion of some this does seem possible; for in one of the latest works on Surgery (Holmes, p. 488) I find that "one of the forms of atheroma is preceded by thickness of the internal and middle coat," and from this the aneurism is traced; as causes, atheroma is considered as "indubitably due to alcohol, and by *many* [the italics are mine] pathologists to be a frequent result of syphilis," "the deposit in the syphilitic variety of atheroma being of a fibroid texture." But if the agencies I mentioned be not the originators of the aortic disease, can "undue vascular tension" supply the place of an exciting cause? Now, it is quite true that the most frequent site of the aortic disease is that where the heart's impulse may be considered at a maximum in the arterial system—the ascending aorta. But what then is to be said of those not at all uncommon instances where the disease is in the descending thoracic or abdominal region, or in the cerebral vessels?—for unquestionably a similar lesion is found in the latter vessels, and under similar constitutional infection to the aortic disease. Surely, too, under these conditions, we ought to expect unfaltering evidence in all cases in the heart itself, both in the aneurismal cases and also in the aortic disease cases; but it is not so. Surely, also, it is more than mere coincidence that the aneurisms and aortic disease so closely connect themselves with the syphilitic cases, and avoid the non-syphilitic, while all are exposed to the same vascular tension from dress, accoutrements, &c. On mere mechanical grounds it is easy to understand how extra internal pressure in an elastic tube would lead to dilatation; but we have to do with an actual thickening, diminishing the calibre of the vessel. There is also another point by which the specific origin of the aortic disease is sought to be negatived, and that is the infrequency of associated specific disease in the heart, by which I suppose gummatous growths in its substance are meant. There are grounds of divergency of structure &c. which might be raised against such a suggestion; but I would only say that, as far as I have been able to extend the inquiry, such disease of the heart is decidedly rare, and, if allowed, would equally negative the specific origin of many lesions acknowledged syphilitic.

"*Undue vascular tension as the chief cause of aortic aneurism.*"—Prior to the appearance of your article I must admit that my inquiries into the subject had not shown me that "hammermen and smiths" suffered more in proportion from aneurism than other classes. I had obtained the impression that, to use the words of a writer on Medicine, "the causes of aortic aneurism were decidedly obscure"; and, in the words of a lecturer on Surgery, "that aneurism is seldom met with among those of the lower classes who labour hard and uninterruptedly." If the statistics of aneurism among the different classes of the community, male and female, in civil life show a clear relation to the arterial tension from occupation, then the point must be conceded; but as far as the army is concerned the dispersion of aortic aneurism throughout its components does not appear to me to bear out such a conclusion. The statistics show it to be generally dispersed, but little range being observed between those in one climate and another or occupation. The infantry man in England with his pack suffers no more than does the cavalry man; the special uniform for India and the Mediterranean, and the relief from many accoutrements, make little, if any, diminution in the aortic aneurismal returns; and Mr. Lawson has shown that there is a marked variation in regiments under the same conditions of dress, exercise, &c. The Russian and German armies are certainly worse off than our own in dress, accoutrements, &c.; but I have been personally informed by several of their surgeons that aortic aneurism is rarely seen among the men. It is true that the three-years' system may somewhat account for this, though on this point we must remember that, as seen in our own army, less than three years suffice to exemplify undue vascular tension from chest constriction in the production, not of vessel lesion, but of derangement of the pumping apparatus, the heart; but a more probable explanation of this rarity of aneurismal disease in these foreign armies is the comparative absence of severe syphilitic infection from rigid carrying out of preventive measures, the severe syphilitic lesions in the museum at Netley striking these surgeons equally with the number of aortic aneurisms there displayed.

Did space permit, it would not be difficult to explain the preponderance of aneurisms in the male sex on other grounds than undue vascular tension as a chief cause, and much also might be said upon the excess in the army as compared with civil life; but as you have brought the latter statement especially against my deduction I cannot quite pass it over in silence. Let it be remembered that we are considering the causation of aortic aneurisms in the first half of life, between twenty and thirty-eight years of age; and for the purpose of making a right comparison it is necessary to have clear and undoubted facts on the frequency and severity (for this is a most important point) of syphilis in civil and military life between these ages, and also on the aneurismal prevalence. Have we these data? Do we in the army, in spite of our comparatively accurate statistics, know the extent of syphilitic infection, and how far do the civil returns conform to this requirement? Again, as regards the aneurisms, it is quite clear that in the army we have only become fully cognisant of their great prevalence by all but invariable post-mortem examinations during late years, and is the same evidence forthcoming from the civil side? The argument against accurate comparison, as opposing a pathological deduction, seems conclusive; but, granting an excess of aneurism in the army, there is sufficient in the pathology of aortic disease to explain this without bringing in as a primary agency an ascribed causation not supported by collateral evidence.

It seems to me that the balance of evidence is decidedly in favour of transferring "undue vascular tension" to a subordinate part in the production of aneurism, powerful only after deterioration of the vessel walls has been brought about by internal agencies. Such a theory rationally explains those cases of aneurism gradually arising, without the possibility of linking them with any external or accidental cause; equally as those cases where sudden arterial tension so acts on the weakened patch of disease as to render the sufferer aware of "something having given way."

The chief deduction of my paper is, that the major number of aortic aneurisms in the army is preceded by a nodular disease of the arterial wall, originated by syphilis, rheumatism, and alcoholism, and that the reason why this sequel (aneurism) of the aortic disease is so frequently met with in army life is due to the secondary fostering influence of sudden extra arterial lesion from accoutrements, exercises, &c. How far this deduction is applicable to the early aneurisms of civil life must be tested by the comparative prevalence of the above mentioned or other exciting agencies of the aortic lesion, supplemented by the degree of vascular tension from occupation to which the deteriorated vessel is subjected.

We have the statement of Sir James Paget, that the opinion among civil surgeons of a connexion of aneurism in early life with syphilis is a growing one. The opponents of my deduction are legion, and hence a corroboration of my paper must be sought in time and future experience, and it is to be hoped that the evidence will be guided by the judicious rules you lay down as necessary to the inquiry. I am, Sir, yours &c.,

Netley, Dec. 9th, 1875. Francis H. Welch, F.R.C.S.

Sanitary Improvement in the Black Country.

The Lower Sedgley Local Board at a recent meeting resolved to adopt the majority of the recommendations made by Dr. Ballard after inspecting part of the Black Country last year, when the sanitary condition of the two Local Board districts into which the parish of Sedgley is divided was of such a notorious description. It has been decided that in Lower Sedgley the duties of the medical officer of health shall be precisely those prescribed by the Local Government Board. Hospital accommodation for infectious diseases is being provided. Inspectors of nuisances are henceforward placed under the direction of the medical officer of health. Measures have been adopted to reform the scandalous deficiency of privy accommodation disclosed at the inspection, and to improve the system of sewage removal. Moreover, the Board express their intention to provide a supply of good water and adequate drainage for their district. Indeed, the intentions of the Board appear to be almost everything that could be desired; but good intentions alone will never cleanse the Augean stable that Dr. Ballard found existing in Sedgley. Let us hope that at last the Local Board in Lower Sedgley are in earnest about sanitary reform, and that the Local Board of Upper Sedgley, the larger part of Sedgley parish, will be stimulated to go and do likewise.

Dr. H. K. Oliver, (Boston.)—He has occupied a high position in his time, but is now very far advanced in the "sere and yellow leaf," and quite beyond work.

Attendance on Medical Men's Families.

To the Editor of The Lancet.

Sir,—In your next issue kindly say whether it is illegal for a medical practitioner to attend his wife in her confinement, or to attend any member of his family in a serious illness, and oblige, Yours truly,

Queen's College, Birmingham, Dec. 1875. J. N. Spiller.

⁎ There is nothing illegal in a medical practitioner attending his wife in her confinement, or any member of his own family in a serious illness. It would be very absurd if it were otherwise. The objections to a medical man attending any serious case in his own family are not at all of a legal character. They have their basis in a very natural feeling in the minds of medical men against seeing patients of their own kin. The judgment almost refuses to act in such cases, and the mind seeks relief from responsibility. Of course we are speaking of cases of some gravity, and not with reference to those numerous minor ailments for which a parent or a husband has many advantages as an adviser. The reluctance to give advice within the domestic circle varies in degree in different men; but, in all, it becomes strong in grave cases, and he is the wisest medical man who errs on the side of readiness to consult a friend as to the case of any one dear to him; and the friend so consulted should always be well chosen, and one for whose judgment respect is felt. For although a medical man may transfer responsibility, he cannot lay aside his opinions; and it is of all situations the most delicate in which, after consulting a medical brother, you have difficulty in assenting to the course he recommends.—Ed. L.

PROF. DITTEL'S OPINION OF OBSTINATE STRICTURE.

AT a meeting of the Medical Society of Vienna on Nov. 5th, 1875, Prof. Dittel exhibited a patient on whom he had performed hypogastric tapping for a retention which had lasted six days (?). The professor had an apparatus constructed for this patient, very similar to that we use in this country. Dr. Dittel (in the *Allg. Wien. Med. Zeitung*) broadly expresses the opinion that when patients are suffering from catarrh of the bladder and enlarged prostate, they would do well to have their bladder punctured at the hypogastrium; and, in order to live long, to wear an apparatus for life, which allows the urine to be received in a receptacle placed under the clothes. This is rather a severe measure for a remediable complaint.

L. J. E., (Cambridgetown.)—Croup is a disease of childhood. It is possible that the attacks may be of an asthmatic character or of nervous origin. At any rate we would suggest that our correspondent should consult some physician, and be guided by his advice.

THE paper of *Dr. James Middleton* (Stow) shall be published.

Dr. McLeod, (Calcutta.)—An article on the subject has been for some time in type, but has been deferred owing to the pressure of other matter.

P. R. S.—Certainly not.

Dr. Crutchley.—We cannot afford the required information, except by saying that the same principle, with an important improvement, is being carried out by a Ventilating Company at 115, Victoria-street, S.W.

POST-MORTEM EXAMINATION OF THE REMAINS OF HARRIET LANE.

IN consequence of the great pressure on our space this week, we are compelled to postpone the publication of the concluding portion of Mr. T. Bond's Clinical Lecture on the Remains of Harriet Lane.

COMMUNICATIONS, LETTERS, &c., have been received from—Prof. Marshall, London; Mr. Bryant, London; Dr. Southey, London; Mr. Hutchinson, London; Sir Dominic Corrigan, London; Dr. Handfield Jones, London; Prof. Stokes, Dublin; Dr. Headlam Greenhow, London; Mr. T. Holmes, London; Dr. Owen Rees, London; Dr. Murchison, London; Dr. Basham, London; Mr. Lawson, London; Mr. Rivington, London; Mr. Gamgee; Mr. J. Lane, London; Dr. Andrew Clark; Dr. B. W. Medical Diary for the ensuing Week.

Monday, Dec. 20.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

ST. MARK'S HOSPITAL.—Operations, 9 A.M. and 2 P.M.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

MEDICAL SOCIETY OF LONDON.—8½ P.M. Discussion on Mr. Maunder's Case of "Excision of the Elbow-joint."—Dr. Lauder Brunton, "On the Physiological Action of Alcohol."

Tuesday, Dec. 21.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 3 P.M.

PATHOLOGICAL SOCIETY OF LONDON.—8½ P.M. The following Specimens will be exhibited:—Hæmorrhagic Periostitis; Fatty Tumour of Spinal Cord; Injury to Radius from Fracture; Deformity from Rheumatic Gout; Recurrent Epithelioma; Cancer of Heart and of Supra-renal Capsules; Cancer of both Breasts and of Right Ovary; Tumour of Clavicle; Aneurism of Aorta; Arrest of Development of both Forearms; Report of Sequel to Dr. Walker's Case of Recurrent Sarcoma of Leg; Embolic Infarct in Heart Muscle; Aneurism of Heart; Aneurism of Mitral Valve; Displaced Kidney; Epithelioma of Chin (living specimen); Epithelioma of Tongue; Sarcoma of Sciatic Nerve; Cancer of both Breasts and of Ovaries; &c. &c.

Wednesday, Dec. 22.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. MARY'S HOSPITAL.—Operations, 1½ P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at 1½ P.M.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.

LONDON HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2½ P.M.

Thursday, Dec. 23.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

Friday, Dec. 24.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1¼ P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, Dec. 25.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

A Clinical Lecture

ON

THE PULSE: ITS DIAGNOSTIC, PROGNOSTIC, AND THERAPEUTIC INDICATIONS.

Being Lecture III. delivered at St. Mary's Hospital in the Summer Session of 1875,

By W. H. BROADBENT, M.D., F.R.C.P.,
PHYSICIAN TO THE HOSPITAL.

Gentlemen,—I come now to Renal Disease as a cause of high arterial tension. This condition is most marked in connexion with contracted granular kidney, but is present in a greater or less degree in all affections of the kidneys, except, perhaps, in amyloid disease, when, unless there is desquamative nephritis as a complication, or general arterial degeneration, the tension may not be great. In tubercular or scrofulous disease of the kidneys there appear to be differences; for I have sometimes found the arterial tension high, sometimes not.

It is with respect to the state of the vessels in contracted granular disease of the kidneys that there has been a controversy between Dr. George Johnson and Sir Wm. Gull and Dr. Sutton. Dr. Johnson, in his original investigations which first gave us precise knowledge of the different forms of kidney disease, noted the thickening of the minute arteries of the kidney in this affection. More recently he found that not only were the branches of the renal artery thickened, but that a similar condition of the minute arteries existed throughout the body—in the meninges of the brain, in the skin, in the gastro-intestinal mucous membrane, and elsewhere; he found, moreover, that the thickening consisted primarily and chiefly of hypertrophy of the muscular coat. These were no barren discoveries in his hands, but became the basis of a theory which linked together by a consistent physiological or pathological explanation the previously isolated phenomena of this form of disease. According to this the kidneys, from gradual loss of the secreting epithelium, fail to remove effectually the urinary constituents, leaving the blood contaminated thereby. The arterioles, to protect the tissues from blood thus rendered impure, resist its passage by contracting, while the heart, meeting with unwonted resistance, puts forth increasing energy; and the result of this contest between the heart, on the one hand, and the minute arteries, on the other, is hypertrophy of the muscular tissues of both.

My way of describing the mode of causation of this hypertrophy is a very imperfect representation of Dr. Johnson's views, and is open to objection on various grounds, as involving unproven theory, and as teleological, assuming that a process *is* because it is useful, or that a process is useful because it *is*; but I have had to sacrifice exactness of expression and completeness of exposition to brevity. It seems, again, a *reductio ad absurdum* to represent the heart and arteries as engaged in this contest, which is damaging to both alike, in the interests of the system generally; but the high arterial tension thus generated, though ultimately tending to shorten life, is, after all, conservative, for by increasing the flow of urine and producing the diuresis which accompanies this disease it postpones the catastrophe of uræmia which would otherwise speedily overtake the patient.

The rival theory of Sir W. Gull has a clinical basis. At a certain time of life it is very common for men to begin gradually to lose flesh, colour, and strength; they suffer from indigestion, the appetite fails, and the bowels act sluggishly; they become apathetic or irritable, disinclined for exertion and incapable of it; the muscles waste; the skin is thin, loose, and dry; some remains of colour persist perhaps in the cheeks from enlarged capillaries, but the temples and the rest of the face acquire a somewhat sallow hue, and the lower eyelids are more or less puffy; often the mucous membrane of the mouth is more anæmic than might be expected from the colour of the face, and there is a deficiency of buccal fluid and a slightly furred tongue. All this time the urine is abundant and clear—perhaps a subject of self-gratulation to the patient; but it will be pale and have a low specific gravity; there may for a long time be no albumen in it, or a trace may come and go from time to time, but eventually albumen is habitually present, and the case resolves itself into well-characterised Bright's disease.

Sir W. Gull and Dr. Sutton, like Dr. Johnson, find in a case of this kind the arterioles thickened, but, say they, the thickening is not hypertrophy, but degeneration. The change in the arterioles they describe as hyaline-fibroid, the disease they name arterio-capillary fibrosis, and the sequence of events they consider to be primarily arterio-capillary degeneration, and secondarily a general fibroid change, in which the kidneys share, so that the kidney disease is not the cause, but the consequence, of the condition of the vessels.

Now of the truth of this clinical history, with the comparatively late appearance of albuminura in many cases of chronic Bright's disease, there can be no doubt; but I agree with Dr. Johnson in disputing the inference drawn from it. First as to the fundamental fact—the nature of the change in the arterial walls as revealed by the microscope after death: is it hypertrophy, or is it degeneration? On the one hand, Dr. Johnson shows an increase in number, size, and distinctness of the nuclei of the muscular fibre-cells, which cannot be mistaken for anything else, and cannot be manufactured by any mode of preparation; on the other, he shows that the swollen, translucent, structureless, or finely fibrillar appearance which Sir W. Gull and Dr. Sutton exhibit as hyaline-fibroid degeneration is, to say the least, producible by the methods of preparation they adopted, and is probably the result of obliteration of the structural characters of the arterial coats. We are asked to suspend our judgment pending the production of further evidence; but I do not see how the unequivocal demonstration of increased muscular tissue can be explained away. With the muscular tissue there will also inevitably be increase of fibrous tissue, which may swell up and obscure the muscular fibres under the use of certain reagents; but this does not prevent the hypertrophy of muscular structure from being real.

But the question does not rest simply on microscopic evidence. If the change in the arterioles were degenerative, the usual physiological and pathological contraction and relaxation of their muscular fibres could not possibly occur, and there could be no changes in the diameter of the vessels or variations of the arterial tension so caused. Now it is certain that the arterial tension is subject to modifications even in advanced Bright's disease. My attention was first forcibly called to this fact in an interesting case which was the subject of a clinical lecture in the winter session of 1871-72[*] The patient was a woman, six months pregnant, under treatment for albuminuria, who died shortly afterwards of apoplexy, and was found to have contracted granular disease of the kidneys. She presented the phenomena of extreme arterial tension, and I was in the habit of demonstrating in her case the characters of the pulse attending this condition. One day, after telling my class as we approached the bed what to expect, I found, on placing my hand on the wrist, that all the indications of high tension had vanished. This was because she was suffering from a smart attack of pyrexia, with the subsidence of which the tension returned, ultimately, as I said, proving fatal by giving rise to apoplexy. I have repeatedly made similar observations since, and when the subject of arterio-capillary fibrosis was coming on for discussion at the Medico-Chirurgical Society, these cases suggested to me an experiment which was entirely confirmatory. This was to administer nitrite of amyl in a case of well-marked chronic Bright's disease, and note the effects on the pulse. Pulse tracings taken before and after the inhalation demonstrated unequivocally the relaxation of the arterioles.

The truth is, or, I ought rather to say, my firm conviction is, that the clinical history, traced by Sir William Gull as that of arterio-capillary fibrosis, which I have just imperfectly reproduced, is a history, not of arterial degeneration, but of arterial tension. From the first the pulse is small, long, and hard, and the cardiac signs of arterial tension first interpreted by Dr. Sibson are present; the

No. 2730.

first sound is reduplicated over the interventricular septum, and at the right second space the first sound is muffled, the second (aortic) intensified or accentuated. But the abnormal state of the circulation can be reversed, and that not only by pyrexia, but by treatment. Allowed to continue long enough, it may give rise to arterial degeneration, and this degeneration becomes the great source of danger, but the degeneration is not primary, and can be prevented. One of the cases I related in my last lecture is a typical illustration of the clinical history under consideration.

The kidney disease, then, is not a result of vascular degeneration. But there is another point to be considered—Is it the result of arterial tension? The arterial tension is antecedent in point of time to the renal disease. Does it stand in a causal relation to it? or are the two conditions—the arterial tension and the structural change in the kidneys—concomitant results of a common cause? The interesting facts adduced by Dr. Mahomed in his paper on the pre-albuminuric stage of acute Bright's disease—that after scarlet fever there is, with rising intravascular pressure, first escape of blood-crystalloids, and then of blood-albumen—would seem to point in the direction of a causal relation between the two; but I have come to the conclusion that an impure state of the blood is the cause both of the resistance in the capillaries and arterioles which gives rise to high arterial tension, and of the morbid change in the kidneys.

A subordinate question is whether the resistance to the circulation of contaminated blood is primarily in the capillaries or arterioles — whether, that is, there is first obstruction in the capillaries, the contraction of the arterioles being secondary, or whether the narrowing of the minute arteries is the sole cause of the obstruction. Of course this brings up the entire subject of the capillary circulation, how far the mutual attraction of the blood and tissues operates to facilitate or hinder the passage of the blood, and this is not to be discussed within the limits of a clinical lecture; but I may say that I have come to believe that, while as a rule the action of the arterioles is direct, and not merely secondary to resistance in the capillaries, there are cases in which the resistance is capillary, the arteries yielding to the pressure of the blood within them.

I shall not occupy you long by illustrations of the association of high arterial tension with disease of the kidneys. The subject is one which I have considered here before, but it is strictly within the scope of this lecture to refer to cases in which the pulse has at once given the clue to the kidney disease. Most of you will remember the case I have already mentioned of a man, Henry C——, aged thirty-three, who applied for admission suffering from pain in the head, vomiting, and impairment of vision; he reeled and staggered also, exactly like a drunken man, and could not walk without support; his speech, again, was thick. He presented a complete picture of cerebellar disease. I sent him to the ward at once, with the remark that there was apparently disease of the cerebellum, probably, from his age and appearance, syphilitic, postponing examination till we could go into the case fully. When I came to his bedside, however, expecting the symptoms and history of an intracranial affection, I had scarcely placed my hand upon the pulse when my first-sight diagnosis fell to the ground. I saw I had to deal with renal disease; the urine was examined and found to be albuminous, the ophthalmoscope showed us albuminuric retinitis, instead of optic neuritis or ischæmia; the headache, the vomiting, the loss of vision were uræmic, and ultimately we had post-mortem demonstration of contracted granular kidneys.

In November, 1873, a former student of this hospital, one of our very best men, sent a clergyman to consult me on account of headache, attacks of giddiness, and impaired sight. Prepossessed with the idea of cerebral mischief, he had overlooked the contingency of renal disease, and had never examined the urine. Here, again, the pulse, long and hard, the artery standing out among the surrounding structures, at once suggested the diagnosis of kidney disease, which was confirmed by the presence of retinal hæmorrhages, a clouded disc, and the familiar white spots round the disc and yellow spot. The diagnosis thus made was verified by the state of the urine, in which, however, at this time there was the merest trace of albumen. Later the symptoms of Bright's disease became more marked, obstinate vomiting being prominent among them, and the patient died a short time ago.

I am reminded of another case in which I was called in consultation to a case of periodic vomiting in an old lady. Her pulse, small and weak, but with all the characters of tension, suggested an examination of the urine, which, as I had anticipated, was found to be albuminous. The vomiting was uræmic.

The examination of the urine is almost a matter of routine, but in both these cases it happened to be omitted. You are aware, however, that albumen is not always present in the urine in contracted granular disease of the kidneys; in the early stages it comes and goes, and later may occasionally disappear. You will see, therefore, the importance of having so clear an indication in the state of the pulse.

Gout and allied conditions of system as a cause of arterial tension.—The term "suppressed gout" is a convenient refuge for ignorance and uncertainty; it is accepted by the public as a sufficient explanation of any chronic or recurrent ailment, or, indeed, of anything and everything, and accordingly it is freely used by medical men. The expression, often spoken of contemptuously, has, however, considerable vitality, because it carries a certain amount of truth. Originally it embodied a conclusion formed from profound clinical observation, and, if it were not abused by indiscriminate application to all kinds of complaints, would be very useful and valuable. In gout, as you are aware, the oxidation of nitrogenised waste, instead of going on to the formation of urea, has stopped short at uric acid, which accumulates in the blood and constitutes a poison to which the attacks of gouty inflammation are due. This, at any rate, is the theory which, if not demonstrably true in every point, is an excellent working hypothesis. But the destructive metamorphosis may fall short even of uric acid, and the blood may be contaminated by a variety of imperfectly oxidised matters. The presence of these impurities in the blood gives rise to the most varied consequences: frank acute gout, chronic gout with the formation of gouty concretions in the joints, on the ears, in the conjunctiva; the less honest forms of gout, pains in the toe, the heel, the loins, the head; attacks of vertigo, irritability of temper, loss of the faculty of attention, palpitation of the heart, cough and shortness of breath, dyspepsia, gravel or stone, inflammation or irritability of the bladder, eczema, and other skin affections. Besides these there are the so-called attacks of gout in the stomach or head, and sudden and extensive congestion of the lungs. After this list you will no longer wonder that everything is referred to suppressed gout. There is one feature, however, common to the whole range of these affections—high arterial tension. Nitrogenised waste, at whatever stage of arrested oxidation, appears to provoke resistance to the passage of the blood through the capillaries and minute arteries, and this affords us the clue which guides us through the maze and gives precision to our ideas.

We are now dealing, as you will see, with the main cause of the two serious forms of disease we have already considered—degeneration of arteries and chronic granular contraction of the kidneys; and what makes it more important is, that at this stage we have the opportunity, not for palliative only, but for remedial treatment. The arterial degeneration is a direct result of the strain upon the walls of the vessels by excessively high tension. As to the renal disease, we cannot, as I have already said, speak so positively; we cannot say definitely whether it is produced by the state of the blood acting injuriously on the epithelium of the tubules, or whether it also is a consequence of high arterial tension.

The following are some of the cases I have seen which may serve to illustrate different phases and stages of suppressed or spurious gout.

I was called in March, 1873, to see a gentleman aged about sixty-four, who was suffering from cough. He held a high position in the Colonial Service, and had spent a great part of his life in hot climates. He was supposed, on that account, to be susceptible to cold. He was stout, good-looking, and of very dignified appearance, but singularly stolid, dull, and uncommunicative. I permitted myself, indeed, to make certain mental reflections on the kind of King Log sent out to administer our colonies. His symptoms, however, were not fully accounted for by the slight bronchial catarrh which was all I found on examination of the chest. More particularly my attention was arrested by a high degree of arterial tension, shown by the long, hard, labouring pulse of 84, and by the vessel remaining full between the beats. There were also the cardiac signs of high tension, a reduplicated first sound near the apex, and an accentuated aortic second sound. By pushing my inquiries, I gradually learnt that my patient had for some little time been more easily fatigued than usual, had been often greatly flushed after dinner, unaccountably irascible, with lapses of memory at times, and, finally, it came out that in a letter written shortly before my visit there had been the most extraordinary anomalies of spelling, many words having been spelt backwards. Nothing could have been more significant than this train of symptoms associated with arterial tension; they were the premonitions of impending apoplexy; and apoplexy, as I learnt later, was the natural mode of death in his family at about his age. The urine had a specific gravity of 1014, but had a good deep colour, and contained no albumen. The object to be attained, in order to escape the threatened danger, was to bring down the arterial tension. I gave calomel (three grains), with colocynth and colchicum, followed by a saline draught as a purgative, and iodide and citrate of potash with taraxacum; reduced the proportion of meat in the diet, substituting milk and fish, and for a time made dinner a midday meal; no restrictions were needed with regard to stimulants, the patient's habits being almost abstemious. This line of treatment was continued for some little time with the effect of removing all the unpleasant symptoms, and I found I had done my patient's mental power and social qualifications great injustice. I saw little of him till Feb., 1874, when I was urgently called one evening, and found that, after similar warnings, he had partially lost power in his left limbs; the left side of the face was slightly paralysed, and the speech very thick and indistinct; there had been some mental confusion, but no loss of consciousness. A similar line of treatment was adopted, and now the dinner hour was permanently established at 2 P.M. Improvement again followed, but it was long before the face recovered itself, and, indeed, a slight inequality is still to be detected. In Feb., 1875, my patient lost all appetite, and the tongue was much furred; there was a certain degree of tension in the pulse, but not so much in my judgment at the time as to warrant the free purgation I had previously employed. I gave aperients and bitter tonics without much effect. My patient fasted strictly through Lent, and lost considerably in weight. After Easter I was asked to see him on account of slight bronchial catarrh. While recovering from this he was seized with severe influenza; and just as he seemed to have shaken off this, and before he left his bedroom, a sudden and violent attack of congestion of the lungs supervened, which nearly proved fatal within twenty-four hours. My treatment of the last complication was dictated by my previous knowledge of the case, and was of a kind I should not have ventured to adopt without it. The congestion of the lungs was simply another consequence of the blood-contamination, of which the arterial tension had formerly afforded evidence; but the tension had lately been less manifest in consequence of weakness—had, in fact, been disguised. Recognising this, I resorted as before to very free purgation, and relief came when this was obtained. Here we reach one of the most interesting points in the case. The convalescence was not satisfactory; the temperature subsided, there was free and loose expectoration of rusty muco-purulent matter, but the appetite did not return, the tongue did not clean, the pulse was weak but long, and there was no recovery of strength till one day there was pain in the ball of the great toe. A mustard poultice was applied, and the patient had his first attack of gout, which was perfectly characteristic, and, considering the circumstances, remarkably severe. After this he was well almost at once, and remains well up to the present time. Here residence in a hot climate, a vegetable diet, and abstinence from the heavier wines, had prevented the full development of gout in a constitution strongly predisposed by hereditary tendency; but a return to this country and to English habits of life, the consumption of more animal food, and the diminished cutaneous excretion, had speedily led to the accumulation in the blood of imperfectly oxidised nitrogenised waste and its consequences. The truth of the inferences I had drawn as to the danger arising from the arterial tension, and as to the cause of this tension, was fully established by the course of events. The occurrence of a first attack of gout after the treatment pursued was remarkable, and indicated, in my opinion, that the metamorphosis of nitrogenised matter had stopped short of the formation of uric acid.

I have had another interesting case under observation recently, which I may briefly relate. A medical man in the country returned home one day last April, about 2 P.M., from an unusually long and cold ride. He took some soup and a glass of sherry, and found, as he thought, that the wine got into his head, for he felt giddy and had to lie down; his speech was thick; he was violently sick; and it was some little time before he could proceed to the remainder of his day's work; and when he tried to walk it was noticed that his left limbs had lost power in some degree; they felt numb, also, at first, and later were in a state of hyperæsthesia. One medical friend said it was "biliousness"; another thought more seriously of his condition, and he came to town to consult me a week after the attack. He was the youngest of a healthy family of sixteen—healthy, that is, except as to a strong gouty tendency. He had a large country practice, was of active habits, worked very hard, was abstemious both as to food and alcoholic drinks; but notwithstanding this he had become decidedly stout, and had from time to time had gouty symptoms. The vertigo and sickness might, of course, have been due to gastric or hepatic derangement, had they been the only symptoms; but the loss of power and sensibility and subsequent hyperæsthesia, and the thickness of speech, remains of which existed when I saw him, were significant of some cerebral mischief; and the pulse gave evidence of very high arterial tension, being hard, long, and rather small. Here, rest from worry, mercurial purgatives, potash salts, a farinaceous and fish diet, with weak spirit-and-water, or water only, as drink, have resulted in an effectual lowering of the vascular tension, loss of redundant fat, and removal of the symptoms. A too rigorous application of the principles laid down, indeed, led to attacks of giddiness from imperfect supply of blood to the brain; and I found it necessary to recommend citrate of quinine and iron for a time, with iodide of potassium.

In the following case, I have no special reason for saying that there was gout, but the patient was, I believe, on the verge of apoplexy. He was seventy-seven years of age, but remarkably hale and vigorous, and would have passed well for sixty. He had been suffering for six weeks from sleeplessness and a feeling of extreme restlessness; naturally, also, he felt weak and worn in consequence. Tonics had been prescribed, but had not suited him; and he had taken chloral and bromide of potassium, obtaining by their means an occasional night's rest, but no efficient relief. His appetite was good and the bowels regular—indeed he rather prided himself on his management of the bowels; he complained a little, however, of indigestion. I found in the pulse evidences of an extraordinary degree of tension, together with senile change in the vessels, though less than might have been expected; the artery large, cord-like, slightly uneven, firm, capable of being rolled under the fingers, and it could be followed half-way up the forearm, the pulsation being long and strong. Nothing could be more full of danger than this condition at the time of life. I gave, therefore, purgatives more freely than usual. After three or four doses the evacuations became so frequent and free that I feared I had carried the treatment too far. I found, however, that they were not liquid, but simply extremely copious, soft, dark stools; there had evidently been great fæcal accumulation, notwithstanding my patient's assiduity in his attention to his bowels. It was some little time before his system regained its equilibrium; but the tension was quickly reduced, and the restlessness passed off. I attributed the sleeplessness to the high blood-pressure, which overcame the tonic contraction of the cerebral arteries, by which the anæmic condition of the brain essential to sleep is secured. Persistence of this degree of pressure must, I think, have resulted in rupture.

But apoplexy is not the only danger to which the arterial tension of retained nitrogenised waste gives rise. The heart may cease to be equal to the struggle against the increased resistance and become dilated, especially if there be degeneration of its structure. You know the usual consequences of this condition: breathlessness on exertion, then cough, with paroxysmal and habitual dyspnœa, œdema, general dropsy and all its miseries. In an early stage, with shortness of breath and cough, it is not uncommon for dyspnœa to come on at 3 or 4 A.M., compelling the patient to sit up, and perhaps pass the remainder of the night in this position. This speedily leads up to further symptoms; but when it depends on arterial tension, as is often the case, it may be relieved by treatment which removes this condition. I have now under observation a gentleman, aged seventy-eight, who, notwithstanding his years, is gradually recovering (has now, September, quite recovered) from severe nocturnal dyspnœa. He is crippled by chronic gout, has a well-characterised senile pulse, and a weak heart. The treatment has been a free resort to aperients and a cautious administration of digitalis and iron. In the case of a lady aged sixty-four, first seen in January of this year, who suffered greatly from this form of dyspnœa, together with harassing cough, complete relief was afforded by the removal of arterial tension by similar means. These cases are worthy of relation in detail had I the time, and I have notes of many others equally worthy of your attention: one, for example, in which I have in the course of six or eight years watched the gradual development of disease of the aortic valves under the influence of strain from arterial tension in a gentleman, the subject of gout. In another case, sent to me from the country in May, the patient had suddenly become liable to dyspnœa, attended with lividity of face on the slightest exertion; the mode of life and clinical history having been exactly that of imperfect nitrogenised elimination and arterial tension. This gentleman had been seriously injured by Bantingism. I can only mention these few illustrations; but I may put in a few words the lesson to be learnt from them. It is, that when the heart shows signs of weakness, and especially when there is reason to believe that there is dilatation of its cavities and degeneration of its muscular walls, if there is any degree of arterial tension, the most effectual relief you can afford is to diminish the peripheral resistance. This can best be done by aperients, and by none so well as by pills containing one or other of the mercurial preparations; afterwards iodide and citrate of potash, or iron and digitalis, or tonics may be given. There is often a degree of debility which seems to contra-indicate purgatives altogether; but it will be found that the powers are oppressed rather than depressed, and that the weakness is apparent rather than real. Tonics in these cases only do harm until after the action of purgatives and other eliminants, when also digitalis may find its opportunity; but frequently, when you cannot strengthen the weak heart, you can give it less to do, and so make it equal to its work.

I proceed to illustrate other effects of retained nitrogenised effete matters with peripheral resistance to the circulation and high arterial tension.

A barrister, thirty-five years of age, consulted me in November, 1874. He was beginning to succeed in his profession, but his prospects were threatened by his state of health. After any heavy work, or an appearance in Court, he had palpitation of the heart and throbbing in the neck and head, with a feeling as if he were about to faint, rendering it necessary to take some stimulant; he would also be entirely sleepless at night. This had been attributed to weakness, and he had been taking meat three times a day rather largely at each meal, with a liberal allowance of sherry. Notwithstanding this his symptoms increased upon him. His appetite was good, his bowels regular, but the tongue was white and indented. I found the pulse full, long, and hard, and the aortic second sound unduly loud, and took these as my indications for treatment. I gave him a gentle aperient pill for four nights in succession, and afterwards every second night. In addition, I ordered phosphate and carbonate of soda, with tincture of ginger in infusion of calumba, and revolutionised his diet, allowing meat and wine (claret) only once a day; breakfast and lunch to consist of milk and farinaceous food. He got well at once.

In the last case there were no specially gouty family antecedents, and the choking of the blood with nitrogenised waste was a direct result of the mode of life. When there is hereditary tendency to gout, imperfect metamorphosis and elimination of nitrogenised matters occur much more readily, and sedentary habits, without any mistaken system of diet, or very moderate indulgence in beer or the stronger wines, with a liberal, but not excessive, amount of flesh meat, will, in spite of an active out-door life, result in the development of a gouty or pseudo-gouty state of system. I have been astonished to see how early in life arterial tension is met with in the children of a gouty parent. I have found it well marked at twenty-one, and seen prominent and tortuous temporal arteries at twenty-four, associated with unaccountable feelings of weakness, weariness, and depression, headaches, loss of application and of interest in the ordinary pursuits and enjoyment of life, and other like symptoms. I will not give these cases in detail, but, instead of them, the following, which illustrates the same point.

A young surgical friend, about thirty-two years of age, consulted me on account of lassitude, inaptitude for work, loss of energy, headache, and other vague symptoms. I gave him the advice we always give each other—that is, to take a holiday. He took one, and was better. By-and-by he came back again with the same story, and he was now uneasy about his heart and lungs, had morning cough, and was sooner out of breath than usual. He could not always be going away on holiday, and I went more carefully into his case. He was remarkably strong physically, but had not quite the colour he ought to have had, took less exercise perhaps than formerly, but still played cricket. His appetite was good and bowels regular. There was nothing particularly wrong that I could see till I placed my fingers on the pulse, when I found a largish cord-like artery standing out among the other structures, and traceable far up the forearm, the pulsation of course long. It instantly flashed upon me that his father was the subject of old-standing gout; the cause of his ailments was clear, fortunately the cure also. I recommended the treatment with which you must now be sufficiently familiar, and forbade my young friend his beer. In a week his arterial tension was reduced, and the symptoms were gone. Upon my happening to remark that beer would at once send up the tension again he volunteered with great alacrity to make the experiment, but to this I did not give my sanction, and he confesses that he is amply compensated by his improved health for the sacrifice I imposed on him.

It is time now that I should say something more definite of the treatment you have seen me so often recommend, and give my reasons for adopting it. The aperient pills are sometimes the ordinary calomel and colocynth, or blue pill and colocynth or rhubarb pills, with perhaps hyoscyamus; sometimes colchicum or ipecacuanha is added. One or two pills will be taken nightly for two, three, or four consecutive nights, or on alternate nights, or twice a week, followed in the morning by a saline draught—sulphate or phosphate of soda, a Seidlitz powder, a dose of some aperient mineral water or of white mixture. The strength of the purgative and the frequency of its repetition will depend on the urgency of the symptoms, the degree of constipation, and many other circumstances. At the same time, I have generally given a mixture containing potash salts; the iodide, two to five grains; and citrate, fifteen to twenty-five grains, with spirit of ammonia and some vegetable bitter, as taraxacum, calumba, hop, gentian, or the like; or, instead of potash, soda salts, the carbonate or phosphate in a similar vehicle. The object in view is the reduction of the arterial tension, and this is effected to some extent by purgation as such, which withdraws a certain amount of fluid from the blood, and relaxes the vascular system of the gastro-intestinal mucous membrane. But while any purgative will do so much, the effect will be imperfect and temporary unless the nitrogenised waste, which is the cause of the obstruction in the capillaries and arterioles, is eliminated. Now the liver is the great organ and instrument of metamorphosis; urea and uric acid are believed to be formed here, and on the efficiency of its functional action certainly depends the due elimination in the urine of the products of the disintegration of nitrogenised compounds. Mercury has long been supposed to act specially on the liver, and though experiments on animals have appeared to negative this idea, it is matter of observatian that mercurial purgatives bring away darker and more bilious stools; it is also matter of observation that they produce a more marked and lasting effect on undue tension in the arterial circulation. I was taught as a student that other purgatives would do all the good which could be obtained from blue-pill and calomel without the risks said to attend the administration of mercury, and for a long time I was altogether sceptical when people who called themselves bilious insisted on the superiority of their favourite blue-pill. After a time, however, I was compelled to admit that the mercurial purgatives afforded a relief which no others did, but I only understood it when I began to observe that they had a greater effect on arterial tension. At present we must take our stand simply on the clinical fact that purgatives containing some preparation of mercury have this effect of lowering arterial tension. The explanation—namely, that this is produced through the influence of the metal on the liver conducing to a more perfect metamorphosis of nitrogenised matters—we hold less firmly. We may, if we prefer it, trace the good results to removal of bile from the upper part of the small intestine, which would otherwise have been resorbed and again separated from the portal blood by the liver. The potash salts are given as eliminants, their effects in this respect having been abundantly demonstrated. Diet is of the greatest importance. Meat should be consumed sparingly, its place in supplying nitrogenised food being to a great extent taken by milk and fish. Soups are forbidden. Little alcohol should be taken, and only in the form of the light wines or freely diluted spirit. Water, free from lime salts, should be drunk in large amount.

We have by no means exhausted the subject of gout, pseudo-gout, suppressed gout, and allied conditions. I have mentioned lead-poisoning as a cause of arterial tension—it is in effect a cause of real subacute or chronic gout, with all its attendant evils: chalk-stones, deformity of the hands and feet, contracted granular kidney, heart disease, arterial tension and degeneration of the large and small blood-vessels, apoplexy, &c. It is of course among hospital patients, painters, and other workers in lead, that gout from lead-poisoning is met with, and they have furnished some of the most terrible examples of gouty disease I have met with. There is a "gout pill" which these artisan classes obtain from chemists, which appears to be most effectual in suppressing gouty paroxysms and pain; there is not, therefore, the check on habits tending to produce gout which the paroxysms would impose, while the poison, never eliminated or destroyed by attacks of acute gout, accumulates in the system in an extraordinary degree. I have seen several cases of gangrene of the lungs in individuals saturated in this way with gout, and believe the lung affection to have been due to this condition of system, in which there is apparently a tendency to thrombosis in the pulmonary vessels. It is interesting and suggestive to note that in the case of gangrene of the lungs recently under my care in the hospital we found high arterial tension. The patient, an ostler, was only thirty-eight years of age, had enjoyed good health, said he had been temperate, had not had gout or rheumatism, and was not the subject of lead-poisoning. He died on June 5th, the day after his admission, and the gangrene was found to be due to thrombosis in the pulmonary artery. It would thus appear that the state of blood which leads to thrombosis gives rise to high tension.

I have not time to enter at all fully upon the subject of high arterial tension in pregnancy. It has been well worked out by Dr. Mahomed (to whose paper I would refer you) and by Dr. Galabin. The illustration afforded by pregnancy of the relation between a condition of the blood and arterial tension, and between this latter and kidney disease, convulsions, thrombosis, &c., is, however, too important and too instructive to be passed over. You are aware that during pregnancy the blood of the mother has to carry nutrient material to the rapidly growing fœtus, and to convey away the effete products of its active tissue changes; it is therefore more highly charged both with raw material and waste, and a high tension prevails in the arterial system. You know also that albuminuria is not uncommon in pregnancy; not only is this the case, but contracted granular kidney is sometimes met with in women, for which no cause but pregnancy can be assigned. These are exactly the results we have seen to arise from retained nitrogenised waste. But the parallel can be continued much further. Puerperal convulsions, if not uræmic, are closely allied to uræmic convulsions, and in the production of both, high arterial tension is an important factor. Puerperal thrombosis, again, whether cardiac, giving rise to sudden death &c., or in the iliac veins, producing phlegmasia dolens, is the precise equivalent of the thrombosis we have just been speaking of in the pulmonary artery. You will understand from what I have just been saying that the old practice of bleeding pregnant women was not always injurious; to some it must have been of immense benefit.

One or two other illustrations of the therapeutic indications given by high arterial tension, and we have done with this part of our subject. I have already mentioned the case of a courier now in hospital, who came in with a history of Roman fever, which was not apparently, as we generally find, a euphemism for typhoid fever contracted at Rome. He complained of extreme weakness and depression, and this, with the probably malarial origin of his fever, induced me to give quinine. He did not improve, however; and after a time I determined to take the state of the pulse as my guide, marked high tension having been observed from the first. I gave accordingly aperients and iodide of potassium, with very good effect.

Another case is that of a gentleman, advanced in life, who was hemiplegic from cerebral hæmorrhage, whose helpless condition was made worse by extreme despondency and most distressing delusions. The arterial tension was very high, and, notwithstanding a state of great weakness, I recommended free purgation and iodide of potassium, with small doses of belladonna. His mental and emotional condition improved greatly, and for some time he was much better. After a time, however, he had a series of severe epileptiform attacks, traceable to, or at any rate associated with, a return of high arterial tension. Treatment of the same kind directed to the removal of the tension was followed by cessation of the convulsions, which up to this time had been increasingly frequent and severe.

Affections of the nervous system as a cause of arterial tension. I have left myself scanty time for the consideration of this part of my subject, and yet it is of considerable importance. In the early stages of acute affections of the brain, and throughout chronic affections, there may be very great arterial tension, due to the influence of the nervous system on the arterioles; it has been very remarkable in some cases of cerebral tumour which I have observed. The arterial tension resulting from the disease of the brain may be taken for arterial degeneration, the cause of the disease. More than once I have seen this mistake made, and there is an instance in a foot-note to p. 457 of vol. ii. of Reynolds's System of Medicine. Occasionally unilateral arteriole spasm is found in hemiplegia on the paralysed side; the tension is not, as a rule, very great, and of course cannot be higher on one side than on the other, but the artery at the wrist will be smaller and the sphygmographic tracing different.

In many so-called functional nervous affections there is fugitive or persistent contraction of the minute arteries, and consequent tension. In the hysteric paroxysm the arterial spasm is remarkable, and it is the cause of the pale, limpid, watery urine which is secreted during an attack. In locomotor ataxy the general condition of the minute arteries is one of contraction, which, during the paroxysms of pain to which such cases are liable, amounts to spasm. I have met with this condition of the vessels in what was apparently incipient insanity, in a lady, as shown by jealous delusions, unfounded general suspicions, and violent and eccentric conduct. Here, treatment suggested by the state of the arteries (Calabar bean, iodide of potassium with arsenic, and cod-liver oil) was followed by restoration of the mental equilibrium. I have seen it again in a lady subject to epileptoid paroxysms attended with mental confusion, but not by loss of consciousness. In most cases of nervous breakdown from overwork there is arteriole contraction and high tension, which, however, often fluctuate greatly; in one case lately under my care, that of a distinguished Oxford undergraduate, the fluctuations were remarkable, and were associated with equally striking variations in his nervous symptoms. Where, in cases of this kind, the vascular tension is persistent, I have not found the treatment by purgatives and eliminants successful. I have before me notes of cases in which high arterial tension was associated, in a gentleman aged forty-three, with giddiness and staggering, emotional weakness, loss of the power of attention, and occasional attacks of vertigo, followed by vomiting and stupor; in another gentleman, aged fifty-two, of remarkable natural energy and activity, with loss of vigour and endurance, excitability and giddiness. On one occasion he passed urine in my consulting-room which had a specific gravity of only 1002. The specific gravity of his urine at other times was found to be 1025 and 1018. It contained neither albumen nor sugar. Other notes relate to a youth of eighteen who, for nearly twelve months, suffered from continuous headache with exacerbations; the cardiac and arterial signs of tension were very marked; he had no vomiting, but at one time I thought optic neuritis was setting in. He ultimately recovered.

My experience would lead me to say that while nervous breakdown from overwork is attended with arterial tension, when it is brought on by anxiety, grief, or worry, this is not the case. I do not, however, speak positively on this point.

I must not forget to mention a fact to which Dr. Mahomed called my attention, and which I have verified—namely, that excitement or agitation sends up the arterial tension at once. I think it is simply from the increased frequency and force of the heart's action, which drives blood into the arterial system faster than it can run off by the capillaries at the normal pressure.

Arterial relaxation and low tension.—I have still to consider the conditions of system associated with an unnatural degree of relaxation of the minute arteries and an absence of the normal tension in the arterial system. For the production of tension in the bloodvessels, *vis a tergo*—that is, a certain degree of vigour in the action of the heart—is required; and when the pulse is weak, it is not always easy to say whether this is due to the heart or to the arteries, more especially as the heart loses strength when the arterial tension is habitually low, both because it has less work to do on account of the abnormally diminished resistance to the blood in the capillaries and arterioles, and because its nutrition must directly suffer from the imperfect supply of blood it will receive when the general arterial tension is low. You will remember that we have low arterial tension in most febrile conditions, but we exclude these from the consideration. The characteristic feature of the pulse of arterial relaxation and low tension is its shortness or quickness. In the intervals the vessel cannot be felt at all; it allows itself to be flattened and obliterated and lost among the structures, without offering any appreciable resistance; and when the pulsation comes, the artery seems to start into existence for a fraction of a second, and is gone again. I am speaking now, of course, of cases in which the arteries are not kept full by frequent and powerful action of the heart, as in pyrexia &c. The pulsation may be more or less strong when it comes, and the artery may vary in size, but the distinctive character is the quick or short unsustained tidal wave. In describing the pulse of arterial relaxation, I said it was large, but when the heart is acting so feebly that it does not fill out the vessels it will feel small. A pulse having the characters produced by a combination of a weak heart and relaxed arteries is no doubt what is meant when a pulse is called "shabby."

I cannot speak so definitely of the diagnostic, prognostic, and therapeutic indications of arterial relaxation, as of tension; but one thing I have learnt respecting the cases in which this condition exists is, that they are most unsatisfactory cases to have to treat. It has appeared to me that undue relaxation of the small arteries is sometimes a cause of weakness and nervous depression by permitting undue loss of heat. It is the duty of the arterioles to shut off the blood from the surface of the body on exposure to cold, and so to protect it from being cooled down. When this function is imperfectly performed, the skin and the extremities may be warm, in spite of very low external temperature, but the body must lose heat rapidly from exposure to cold of successive portions of blood sent to the skin, and either the temperature will fall or increased oxidation will be required to keep it up. In either case there is a heavier tax on the system, and only a very vigorous constitution can support it with impunity. A sufferer from depression so produced will exhibit his warm hands and skin as proofs of his excellent circulation. I had some years ago under my care for several successive winters a melancholy giant, almost the very tallest man I ever saw, and proportionately stout. During the summer he was well; no day was too hot for him, and he was capable of considerable and sustained exertion; but in cold weather he was depressed, miserable, incapable of giving his attention to his duties, and continually under the necessity of resorting to stimulants. All this time he was unconscious of external cold, and did not take cold, never wore an overcoat, and his hands were always comfortably warm. He could not understand that this very warmth was a cause and a mark of weakness, and refused to seek the protection from cold which he did not feel to need.

A clergyman, aged fifty-one, having a small country parish, consulted me in October, 1874. He was formerly robust, and had been a boating man at college, but he had been ailing for ten or twelve years, complaining chiefly of indigestion, with low spirits, sleeplessness, and a variety of symptoms and sensations about the head and heart, of which I should fail to convey to you any idea. The appetite was good, and the bowels acted regularly but inefficiently, the motions being pellety; urine apparently normal, but decomposing quickly. He looked thin, pale, and haggard, and his tissues were excessively lax. Pulse 90, soft, short, weak, and with no tension at all.

I could not find any cause for the break-down in my patient's health. He was not overworked, lived wholesomely, and was not unduly sedentary in his habits.

I may tell you what I recommended, but little impression was made on his symptoms. I obtained a better action of the bowels by means of a mild aloetic pill, and this having no good effect, tried blue pill, ipecacuanha, and rhubarb. I gave at different times iron, arsenic, digitalis, phosphorus, cod-liver oil, bromide of potassium, sulphate of zinc and extract of hop pills, securing also from time to time sleep by chloral, &c. You will trace the ideas which dictated this treatment; they were to improve the nutrition of the nerve-centres, and of the body generally, to raise the tone of the heart and minute arteries, to remove or quell nervous irritability, and to give rest. The diet was of course regulated. I should add that he could not take stimulants. He gave himself a holiday also, while under my care, but with only temporary benefit.

Another case, essentially similar, came under my observation about the same time. The patient, aged forty-five, had been complaining for three years of a dull pain in the head, which set in at 11 A.M., and went on through the day; with it was a kind of pain in the right leg, and, when worse than usual, also in the right arm. He did not sleep well, and was full of apprehensions; was emotional, and cried while describing his sufferings. Appetite good; bowels not open; pulse frequent, very weak, soft, short, and shabby. I only saw him twice, and do not think he was any the better for the treatment I ordered.

These cases would come under the term hypochondriasis, but there were fewer fancied ailments and more deterioration of health than usual. Hypochondriacs go about from one physician to another with their cardiac, hepatic, intestinal, or sexual woes, and one comes to take less note of states of pulse, urine, &c., than one would if they were expected to remain under observation; but I am always glad when I find a pulse of high tension in such cases, as I think there is a better chance of doing good.

I must not leave you under the impression that want of tone in the arteries is always accompanied with pallor and leanness. I have noted it in stout, pale, flabby people, with a soft and inelastic, or a firm brawny skin. I have met with it also in individuals not only decidedly stout, but of an unnaturally high colour, associated with a number and variety of nervous sufferings and nervous symptoms, of which I could give you no idea. No patients are to be more commiserated than some of these, who, looking to the uninstructed eye the picture of health, are the victims of miseries from which actual pain would be an agreeable distraction. What makes it worse is, that so little can be done for their relief. These cases are in special danger from alcohol.

One of the most marked cases of arterial relaxation I ever saw was in a gentleman who a few weeks later became insane. He was then in an extremely nervous condition, apprehensive of sudden death, and often thinking he was dying, causing great alarm and excitement to his family, unwilling for his wife to be a moment out of sight, but irritable, tyrannical, and unkind in his behaviour towards her. He had lost all energy, slept badly, was weak, and soon fatigued. He was tall and well built, looked strong, but his voice was weak, toneless, and monotonous, and his articulation careless or slovenly. His pulse was small, weak, short, and shabby, to an extraordinary degree, and his hands were damp and clammy. He had lived a fast life when young. Accounts as to his recent habits with regard to alcohol were contradictory. I only saw him once, and the next news I had of him was that he was suffering from unmistakable melancholia.

In acute dementia, again, the pulse has been, in the cases

I have seen, exceedingly weak, soft, and short, and the action of the heart frequent and irregular, indicating an entire absence of tone in the vascular system. I have found a marked deficiency of arterial tension in many cases of epilepsy, and have at present two cases under observation in which it is very striking. The pulse is very soft and short, but large and fairly strong, the blood seeming to shoot through the small arteries and capillaries without resistance. Another noteworthy point is that a deep breath or a change of position has an unusually great effect on the heart's action, which is hurried for a few beats, while, if the patient stoops, the face is flushed immediately, as if the arterioles were incapable of resisting the greater pressure due to the lowering of the head, and allowed the capillaries to be flooded with blood. It is difficult to say whether these patients are epileptic by reason of the relaxation of the arterioles or of the absence of the normal cohesion between the blood and tissues, or have this deficient vascular tone because of the condition of the nervous system which gives rise to the epileptic attacks; but, however this may be, I consider that the pulse affords an indication for treatment. Whatever is found to effect permanent improvement in the tone of the arteries and to raise the vascular tension may be expected to do good. If the epilepsy is an effect of the want of arterial tone, the restoration of this may cure the epilepsy; if it is the epileptic condition of the nerve centres which is the cause of the want of tone, a remedy which removes the effect will probably have a favourable influence on the cause. May we not have here some explanation of the good effect of bromide of potassium which has been found experimentally to cause contraction of arterioles? Also of Trousseau's favourite remedy, belladonna? My attention has not been drawn sufficiently long to the connexion between epilepsy and low arterial tension to enable me to bring forward evidence as to the effects in epilepsy of remedies which improve the arterial tone. Years of careful observation will be needed for this. Nor do I find much assistance from looking over my notes of cases of epilepsy. I may refer here to the interesting case of ——, who has just left the hospital. He has worked in lead, and has the blue line on his gums, but has had no colic or other saturnine diseases. He came into the hospital because on stooping, and especially to lift any weight, he became giddy and confused, and almost lost consciousness; and we at once saw, on causing him to bend down, that his bald head, face, and ears became crimson. He was liable also to heat and flushing of the head and face without this exciting cause, and at these times we have found the lobules of the ears of a deep purple colour, and very hot. In this patient the fluctuations of the arterial tension were most remarkable; and our notes, taken at different times, record observations absolutely contradictory. What makes the case more interesting is the fact, discovered accidentally while the experiment was being made with another object, that pressure on the carotids, or on one only, almost immediately induced an epileptoid attack; the face flushed (even when the pressure was applied to the common carotid, which was remarkable), and the features were drawn into a peculiar smile; the patient looked confused, lost consciousness, staggered, and fell back upon his bed with slight general convulsive movements. A few moments later he looked round with a puzzled expression, wondering what had happened. There was no marked change in the size of the pupils at any period. He slowly improved while taking iodide of potassium and tincture of nux vomica; the lead-line disappeared, the flushing and vertigo in stooping were less marked, and the epileptoid attacks were less easily induced. Naturally, we did not repeat this experiment often. The combination in this case of fluctuation in the arterial tension, weakness of the vessels of the head and face permitting of the flushing described on stooping, with liability to artificial epilepsy, is peculiarly interesting as a parallel to the combination associated with true epilepsy. Taking lead to have been the cause of the condition, its action was no doubt primarily on the (sympathetic?) nervous system; and to the state of the nervous system was due the instability of the vascular system. But it is, in my own mind, an open question whether the liability to epileptoid attacks was not in turn an effect of the vascular instability and want of tone.

To make the account of arterial relaxation complete, I ought to consider exophthalmic goitre and aortic pulsation, of which diseases it constitutes a feature, but I must pass them over with a simple mention.

My observations on low arterial tension have been discouraging, and I have as yet had little success to report from treatment, but it sometimes affords an indication which is of service. Many weak nervous women suffering from leucorrhœa or menorrhagia, or worn out by repeated pregnancies or prolonged suckling, or overwhelmed by domestic duties and responsibilities, have with anæmia and debility the pulse of arterial relaxation, and in these cases the addition of digitalis to the iron and other tonics often makes a great difference in the effect. My friend Dr. Fothergill gives these patients bromide of potassium and digitalis, and later quinine and iron with bromhydric acid. I saw them by scores in the out-patient department, but they are almost excluded from the wards by more urgent cases, and I have not yet tried his plan of treatment.

I must bring this lecture to a close. I have been, I fear, diffuse and sketchy, but I have been tempted to take up the subject, perhaps prematurely, by the interest some of you have manifested in it. I have seen you with extreme pleasure acquire thoroughly the art of discriminating between the different kinds of pulse and recognise the indications they afford, and I wish to put you in possession of whatever knowledge I have which may make your skill useful to yourselves and your patients.

ON GELSEMINUM SEMPERVIRENS.

By SYDNEY RINGER, M.D.,
PROFESSOR OF THERAPEUTICS AT UNIVERSITY COLLEGE;
AND
WILLIAM MURRELL, L.R.C.P., M.R.C.S.,
DEMONSTRATOR OF PHYSIOLOGY AT UNIVERSITY COLLEGE.

THIS powerful drug has long been employed in America, and a few years ago was introduced into this country as a remedy for neuralgia by Dr. Wickham Legg. His statements have been amply verified by Dr. Sawyer, Dr. Mackey, Dr. Spencer Thompson, and others. It is said to be especially useful in non-inflammatory toothache and in neuralgia in the nerves supplying the teeth and the alveolar processes of the jaw. In large doses it produces general paralysis. Several cases of poisoning are recorded, some ending fatally.

We extract from the Proceedings of the American Pharmaceutical Association (vol. xxi., 1873) the following account of the effects resulting from a toxic dose:—"The symptoms by which its effects manifest themselves in the animal economy seem to indicate that its energy is primarily exerted on the cerebro-spinal centres, and secondarily on the respiratory apparatus and the heart, the functions of the former ceasing before those of the latter. The motor nerves of the eye are attacked first; objects cannot be fixed, dodging their position; the eyelids become paralysed, drop down, and cannot be raised voluntarily; the pupils largely dilate; there is a feeling of lightness in the tongue; it ascends gradually to the roof of the mouth; pronunciation becomes slurred; then the extremities refuse to support the body, and erect motion without support becomes impossible; the pulse gradually becomes more frequent, rises to 120 to 130 and more beats per minute, is small but regular; respiration then becomes laboured, the mind remaining clear, however. This state will set in about an hour and a half after the ingestion of an overdose of the drug. ...... All the symptoms will disappear after about two hours, leaving no unpleasant effect or derangement of the organism." In many cases of poisoning the patients have complained of double vision, and dimness, even loss, of sight, and the breathing is slow and sometimes irregular and shallow.

In the *Practitioner* for October, 1870, Dr. Roberts Bartholow published an account of some experiments made on frogs, pigeons, and cats. He concludes that gelseminum (*a*) acts chiefly on the motor portion of the cord; (*b*) its paralysing effect is due to its action on the motor centre, and not to an action on the peripheral nerve-fibres; (*c*) it acts also on the sensory portion of the cord, producing at last complete anæsthesia, but this effect in warm-blooded animals and in man is toxic only, and follows the paralysis of the motor functions.

As this drug is now attracting considerable attention in this country, and has been largely used in America for fevers, including ague and influenza, hemicrania, spermatorrhœa, dysmenorrhœa, &c, we were induced to make these investigations, which will be seen in many respects to corroborate the conclusions of Dr. Roberts Bartholow. At first we used the liquid extract prepared in America, which contains some spirit, but afterwards the alkaloid dissolved in water, extracted by Mr. Gerrard, teacher of Pharmacy at University College.

We now proceed to give a short general account of the effects produced by the drug on a frog.

A medium-sized German frog was injected with the drug in the neighbourhood of the posterior lymph hearts. In this, as in all our experiments in which injections were given, special precautions were taken to ensure cleanliness of the apparatus, and freedom from contamination by other drugs. Soon after the administration of the drug the animal became extremely apathetic, and it was found that there was considerable impairment both of voluntary power and reflex action. When placed on its back the frog made no attempt to resume its normal position for a minute or two, and then slowly turned over, often, however, stopping half-way and lying motionless on its side. On touching the eyes they were closed, but some minutes elapsed before they were again opened, and even then the movement was performed with abnormal slowness. The loss of voluntary power and reflex action gradually increased, and the animal soon became perfectly motionless. When placed on its back no attempt was made to turn over. The whole body was limp and flaccid, and the limbs remained in any position in which they were placed, either flexed or extended. On pinching firmly any part of the body, a very feeble and ineffectual attempt to escape was made, the animal, in its unavailing efforts, falling over on its back or sides. The application of the poles of the battery to the limbs excited, in addition to the muscular contraction, faint reflex movements. *Pari passu* with these changes in the nervous system, the breathing became hurried and superficial, and as the paralysis increased, the respiratory movements became more and more shallow, and, finally, with the total abolition of voluntary power and reflex action, entirely ceased. The heart continued beating for a considerable time after the cessation of the respiratory movements.

The rapidity with which these symptoms presented themselves, and the ultimate termination of the cases, varied with the dose administered. Thus twelve minims of the liquid extract injected under the skin of a large frog produced such an impairment of voluntary power that in three minutes the animal was unable to turn over, and in two and a half hours death ensued. In doses of five minims or less, some hours usually elapsed before the establishment of complete paralysis, and the animals frequently remained alive, but perfectly helpless for many days. In one instance, in which a five-minim dose had been given, life was prolonged until the tenth day. Towards the close of this period there was considerable improvement both in voluntary power and reflex action; the effects of the drug appeared to be passing off, and hopes were at one time entertained of the ultimate recovery of the animal. A five-minim dose of the 1 in 20 solution of the alkaloid gave rise to decided symptoms of poisoning in four minutes, and in five minutes later the full effects of the drug were exhibited.

With some frogs there occurred for a short time a peculiar mixed state. Thus, soon after voluntary and reflex power was completely abolished, on irritating one of the limbs, the hind extremities were sometimes shot out, and all their muscles, with those of the back, contracted. This happened only occasionally. Thus, generally, on applying the electrodes to an extremity, only the muscle touched contracted, and none others; but sometimes there ensued the tetanoid condition just described; in a few minutes this ceased. With other frogs there occurred only a slight tremor of some of the muscles of the legs, chiefly those of the thigh. This tremor was at once excited by moving or jerking the body. It was apparently caused by the successive contraction of the muscles of the limb, giving rise to a peculiar flickering, which was readily perceived through the skin. Supposing these phenomena to be due to the influence of the drug, they must be caused by its action on the spinal cord, for they occurred in the posterior extremities after ligature of the abdominal aorta.

Another circumstance also attracted our attention. When the electrodes are applied over the lower part of the spine of a live healthy frog, the hind legs are shot out much in the manner before described. Now it appeared to us that after poisoning by gelseminum the posterior extremities were more forcibly extended, and remained so for a longer time.

We then performed the following experiments to ascertain whether gelseminum paralyses by its effect on the brain, the cord, the motor or sensory nerves, or the muscles.

The paralysis of reflex and voluntary power is certainly not due to the action of the drug on the muscles; for after poisoning, on galvanic stimulation the muscles contracted as energetically as those of an unpoisoned animal; moreover, on several occasions we tied the abdominal aorta or the femoral artery and vein, and twice we severed the thigh, leaving the leg attached to the trunk only by the nerve, and then poisoned the animal, and we found that the muscles subjected to the action of the gelseminum contracted as energetically and retained their contractility as long as the muscles protected from the poison by ligature or section of the vessels.

Neither is the paralysis due to the action of gelseminum on the motor nerves. This, indeed, is proved by the experiments just mentioned, which we now proceed to describe more fully. We tied the femoral vessels on several occasions, and twice we cut through all the structures of the thigh, except the nerve, which alone connected the severed leg with the trunk, and then poisoned the animal by injecting the drug under the skin of the back, in the neighbourhood of the lymph sacs. The paralysis occurred as soon, progressed as rapidly, and became as complete in the limb protected by ligature or section from the action of the poisoned blood as in other parts subjected to the influence of the poison. After complete paralysis we found that the nerves unprotected from the action of the poison conducted as freely as those protected by ligature or section. These experiments show that the poison does not act by its effects on the ends of the motor nerves; but the trunks of the nerves in the abdomen, and above the ligature in the thigh might be affected, and the paralysis produced in this way. We therefore on three occasions ligatured the abdominal aorta, just above its bifurcation, and then poisoned the animal in the manner described, and we found the paralysis progressed in the hind protected limbs as in the anterior, and as in the case of frogs whose hind limbs are unprotected by ligature of the aorta.

There remain, then, to consider the brain, cord, and the afferent nerves. We shall treat of the loss of reflex power separately from that of voluntary power. It is obvious that the destruction of reflex power cannot be due to the effect of the poison on the brain, and as it is not due to the paralysis of the motor nerves or muscles, it must depend on paralysis either of the afferent nerves or the cord. It is not due to paralysis of the afferent nerves, for after tying the abdominal aorta before administering the poison, and thus protecting the hind extremities from its effects, we could not excite reflex action by galvanic stimulation of the hind legs. It therefore appears that gelseminum abolishes reflex action by its effect on the cord.

Does it thus affect the reflex function by its direct action on the cord, or indirectly by stimulating the inhibitory centre for reflex movements? It does not act through Setschenow's inhibitory centre; for, firstly, the abolition of reflex function is too complete to be produced in this way, and, secondly, after producing complete loss of reflex action, we beheaded the frog, and so divided the cord below the inhibitory centre, which is situated in the neighbourhood of the optic lobes, and yet the loss of reflex power remained as complete as before. We therefore conclude *that gelseminum destroys reflex power by its direct action on the spinal cord.*

We have next to explain how the loss of voluntary power is produced. We have shown that the paralysis is not due to the effect of the drug on the muscles and motor nerves, and it is obvious that the loss of voluntary power cannot be produced by paralysis of the sensory nerves. It must therefore be due to the action of the gelseminum either on the brain or the motor tract of the spinal cord. We have no experiments to decide this question, but we offer the following reasons in favour of the view that it acts through its influence on the cord:—(*a*) The loss of voluntary and reflex power proceed *pari passu*. (*b*) The abolition of reflex power being due to the effect on the cord renders it to some extent probable that the loss of voluntary power also depends on affection of the cord. (*c*) In the cases of accidental poisoning where the voluntary power was so complete that the patients could not move a muscle, could not even raise the eyelids, it is recorded that on recovery they asserted that their consciousness was not at all affected. It may be said that if the loss of voluntary power is due to paralysis of the motor tract of the spinal cord, it should not conduct electric impressions. But we may remark that a great difference of opinion exists among physiologists respecting the conducting power of the cord of electric irritation, and it appeared to us therefore unnecessary to perform this experiment.

We have seen that the afferent reflex nerves are paralysed. Are the sensory nerves affected? If the sensory nerves are also the afferent reflex nerves (the view generally held by physiologists), the question of course is answered in the negative. Still we suppose that though some afferent nerves may have this double function, yet there are others which are simply sensory. Are these paralysed, or are the sensory perceptive centres paralysed? In other words, does gelseminum destroy sensation as some writers have supposed, and if so, does it act on the sensory nerves or the sensory tracts of the cord, or on the sensory perceptive centre? These experiments do not enable us to answer these questions, but we may state that as long as voluntary movement remained, the frog seemed to feel pinching and galvanic stimulation, for on the application of either kind of irritation, the animal made voluntary efforts to escape, though after paralysis was marked it required considerable pinching to induce voluntary movement. Was this due to defective feeling or from the paralysis requiring a greater effort to cause movement? We shall return to the effect of gelseminum on sensation, when we treat of its effects on man.

The foregoing experiments prove that gelseminum abolishes reflex, and probably voluntary, movement by its influence on the spinal cord. It may, however, in addition, to a slighter extent, and late in the poisoning, affect the motor nerves. This is the case with Calabar bean, which paralyses the spinal cord, but also slightly the motor nerves. To learn whether gelseminum in any way depresses the motor nerves, we performed the following experiments on three frogs. We tied the iliac artery, and then poisoned the animal; and, after the loss of reflex and voluntary power, we tested at frequent intervals the conductivity of the sciatic nerves to electric stimulation, and we found that the gradual loss of the power of conduction was equal in the two nerves, but that after some time the nerve protected from the action of the poison required a rather stronger current than the unprotected nerve, due, perhaps, to diminished nutrition from arrest of the circulation. Hence we conclude that probably (for our experiments are not numerous enough to settle absolutely this question) gelseminum exerts no influence on the motor nerves.

We may here state that in each experiment in which an artery was tied we ascertained by a post-mortem examination that the operation had been successfully performed.

ON DILATATION OF THE FEMALE URETHRA.

BY ARTHUR W. EDIS, M.D.,
ASSISTANT OBSTETRIC PHYSICIAN, MIDDLESEX HOSPITAL.

THE clinical essay of Mr. Teale, the remarkable case cited by Mr. Hewetson in THE LANCET of December 4th, and the experience of Mr. Heath, recorded in THE LANCET of December 11th, encourage me to publish the notes of two cases that may possibly prove of interest to the profession, as illustrating the necessity of caution in adopting this expedient and also the importance of excluding other possible causes of irritable bladder before resorting empirically to forcible dilatation of the urethra. I have notes of a large number in my case-book, but select the following as illustrative of many others. The conditions most frequently producing irritation at the neck of the bladder, with painful or frequent micturition, apart from any alteration in the quality or quantity of the urine itself, are chiefly vascular growths in the urethra, cystitis, stone in the bladder, passage of small renal calculi, pressure upon the neck of the bladder from an anteflexed fundus uteri, dragging down of the posterior wall of the vagina (as in cases of prolapsus uteri), fissures or cracks in the urethra, extension of malignant disease from the uterus, or malignant degeneration of the bladder itself.

CASE 1.—M. D——, aged forty-two, married, sterile, first consulted me in December, 1872, for irritability of the bladder. Micturition was frequent and attended by scalding. The symptoms had come on gradually during the last month or six weeks, and had lately much increased in severity, the patient being obliged to get up several times during the night to pass water.

Examination of the urine detected nothing abnormal beyond the presence of lithates. On examining per vaginam, there was no evidence of any unusual discharge. The vagina was moist and cool; no vascularity of the urethra was apparent; the uterus was normal in bulk and position. No local lesion likely to account for the symptoms was found. On exploring the bladder by means of a sound, no calculus was felt. The only unusual symptom was soreness of the urethral passage, but, as the patient was very nervous, it was thought at the time to be nothing calling for further attention.

Saline aperients with diuretics and restriction of the diet were enjoined, and the patient urged to resist the desire to micturate so frequently.

As the irritability of the bladder and soreness on micturition persisted, a pair of leeching forceps, about the size of an ordinary quill, was inserted, and the blades forcibly dilated so as to distend the urethra. The little finger being then passed, roughness of the posterior wall of the urethra was detected, but as the operation caused much pain nothing further was done. Later on in the day I received an urgent summons to visit the patient, and found her very weak and faint, lying in a pool of blood and urine. On making a local investigation a distinct jet of bright blood was seen after removing some clots and employing the catheter.

A No. 10 elastic catheter was inserted and left *in situ*, pressure being applied along the course of the urethra by means of cotton wool inserted per vaginam. This arrested the hæmorrhage for the time, but on removing the catheter the following morning, the bleeding recurred. A sound coated with cotton wool and saturated with solution of perchloride of iron was passed per urethram, which again arrested the hæmorrhage for a time, but it was not until a No. 12 elastic catheter covered with cotton wool steeped in tincture of matico was passed and retained *in situ* for twelve hours that the hæmorrhage was finally arrested.

The case caused me much trouble and anxiety, and impressed me forcibly with the risk incurred in resorting to forcible dilatation of the urethra.

The patient convalesced rapidly, regained perfect control of the sphincter within the course of a few days, and had no further symptoms of irritation.

CASE 2.—E. H——, aged eighteen, single, servant, presented herself as an out-patient, complaining of frequency of micturition. During the day she stated that she could only hold her water for about half an hour, and was obliged to get up at least five or six times during the night to empty the bladder. This condition had been gradually coming on during the last two years, and was always worse about the time of her periods, but had been much worse the last six months. Iron, belladonna, bromide of potassium, chloral, ergot, strychnia, and every other likely drug were given at different times, without more than the most temporary benefit. As the condition remained unaltered, she was admitted as an in-patient at the Hospital for Women.

A careful vaginal examination showed that the uterus was anteflexed, though not to a very marked degree. Buchu, uva ursi, triticum repens, alkalies, and acids gave no relief. Confinement to bed, restriction in the amount of fluids, blisters to the suprapubic region, the adjustment of an india-rubber ball inflated with air per vaginam so as to compress the urethra, injection of two-grain doses of morphia into the bladder, and every other available expedient was tried without avail. At this time Mr. Heath saw her in consultation, and suggested rapid dilatation of the urethra. Chloroform was administered and the operation performed; the neck of the bladder being brushed over with a strong solution of nitrate of silver. The symptoms remained unchanged. The urine was passed between five-and-thirty and forty times during the twenty-four hours (as ascertained by the patient pricking a card with a pin every time she made water).

The case now seemed hopeless. The patient's condition was most deplorable. The frequent necessity for getting up during the cold winter nights, the discomfort from constantly wetting her linen, and the offensive ammoniacal odour produced rendered her existence almost unbearable.

Every method of relieving the bladder having been tried in vain, I thought, before discharging her as incurable, it would be well to try the effect of an intra-uterine stem. After some preliminary passing of the uterine sound, a small vulcanite stem was inserted, but was extruded within a few hours. Having made one with a bulbous extremity, this was inserted and was retained *in situ*. Within a few days she had perfect control over her bladder, and before leaving the hospital, some ten days after the insertion of the stem, she could pass the whole night without getting up, and only micturated four or five times in place of forty during the twenty-four hours. She took a place and remained perfectly well, until one day, hurrying to catch a train, the stem came out, when all the old symptoms recurred. She was obliged to come up to town and have it reinserted, and has done so twice during the last two years. During the present month she has written to say how very grateful she is for the relief, and that she remains quite well.

Wimpole-street, W.

Medical Societies.

OBSTETRICAL SOCIETY OF LONDON.

At the meeting on December 1st, 1875 (W. O. Priestley, M.D., F.R.C.P., President, in the chair), the following gentlemen were elected fellows of the Society:—G. R. Cundell, M.R.C.S.; J. F. Eyeley, M.R.C.S.; J. J. Gawith, M.R.C.S.; A. J. Miles, M.D.; J. Musgrave, M.R.C.S.; A. H. Orpen, A.B., L.R.C.P.; and Tyler Smith, M.B. (Hounslow).

Mr. **Oliver Barber** (of Sheffield) exhibited a specimen of Anencephalic Fœtus where the calvaria was altogether absent, and the base of the skull formed simply by the basilar portion of the occipital bone. The laminæ and spines of the upper cervical vertebræ were undeveloped, leaving the spinal canal open. There was no appearance of any spinal cord on dissection, the canal itself being lined by a thin fibrous membrane. There was an enormous quantity of liquor amnii present; the open spinal canal closely simulated the anal aperture.

Dr. **Godson** exhibited a drawing of the Breasts of a Girl, aged eighteen, pregnant seven months, affected with chorea. The inner half of the areola of each nipple was entirely free from pigmentation, that of the outer portions being unusually dark and crescentic in form. The girl was present for the Fellows to inspect.—Dr. **Barnes** said the case was extremely interesting. The symmetrical defect of pigment might be explained by like areas of nerve-distribution. In all probability the altered nervous condition of pregnancy had much to do with pigmentation. Respecting the chorea he (Dr. Barnes) had long since called attention to the fact that under the exalted nervous tension wrought by pregnancy, aided probably by some change in the constitution of the blood, any pre-existing disposition to chorea or other nervous disorder was apt to be evoked. Thus, pregnancy was an exciting cause of chorea.—The **President** inquired whether there was any history of injury from a scald or burn. The case presented the usual characters of some skin eruptions, in that it was symmetrical.—Dr. **Wiltshire** thought the case peculiar and interesting, and worth preserving in the Transactions of the Society, if Dr. Godson would give the coloured drawing.—Dr. **Godson** stated that there was no hereditary tendency to such a condition. The mother had two nipples on one breast.—Dr. **Hayes** thought the fact of chorea and pregnancy existing together was one of much interest. He had seen 100 cases of chorea, and had noted the very marked relation between chorea and rheumatism.

Dr. **Edis** exhibited a specimen of Epithelioma of the Cervix Uteri in Pregnancy, removed post mortem from a patient. She was thirty-three years old, married six years, two children, youngest three years, which she nursed for one year and nine months. Dr. March, of New Wandsworth, had sent the case up to Dr. Edis, at the Middlesex Hospital, in the latter end of June. She was then found to be the subject of epithelioma of the cervix uteri, and was, as near as could be judged, between seven and eight months pregnant. She had had frequent floodings, and a more or less continuous offensive watery discharge. As the patient could not be admitted at the time, the nature of the case and the difficulty likely to occur when labour set in were explained to her, and she was desired to report herself further on. On August 7th she presented herself, stating she was in labour. The disease extended in a crescentic manner round two-thirds of the os uteri. The remaining healthy portion seemed disposed to dilate, and as the pelvis was roomy, it was thought the risks to the mother and child would not be greater than if Cæsarean section, which had previously been contemplated, should be resorted to. Dilatation of the cervix was facilitated by means of Barnes's bags, and at 10 A.M. on August 8th, the cervix having dilated sufficiently, chloroform was administered and the long forceps applied, a female living child (weighing six pounds and a half) being extracted. With the exception of some diarrhœa, the patient progressed fairly well for the first week, when the temperature rose to 105° F., and the patient died on the 21st, a fortnight from the date of delivery.—Dr. **Routh** thought that Cæsarean section ought to be more often performed in these cases; it gave the best chance of life to the child. Where labour was allowed to take place naturally, the death of the mother usually resulted from puerperal fever and sloughing.—Dr. **Barnes** could not assent to the conclusion that the Cæsarean section should be resorted to in every case of cancer of the uterus. The cases cited by Dr. Routh occurred in the Vienna Hospital, where many other causes of puerperal fever were rife. He himself had seen women survive labour complicated with cancer. One woman had been delivered twice. It was not advisable to lay down a general rule.—Dr. **Meadows** stated that his experience entirely corroborated that of Dr. Routh, that the risk to the mother in cases of extensive cancerous disease of the cervix was so great that the Cæsarean section was preferable to any other mode of delivery. He had seen four cases of this kind, and all ended fatally to the mother, while only one child was saved. In one craniotomy had been performed, in two premature labour was induced. He believed that the Cæsarean section gave a better chance to both mother and child in cases where the disease was so far advanced that an operation of some kind was necessary for delivery.—The **President** thought this statement should be qualified by the extent of the disease. He inquired if Dr. Meadows really meant that he would perform Cæsarean section in *all* cases of labour complicated with malignant disease of the cervix uteri, for if so, he believed this was an opinion which most practitioners would think required some qualification. While not doubting the propriety of this operation in cases where the passages were much obstructed by morbid growth, or where serious laceration of the parts must ensue if delivery was effected through the natural passages, he could not concur in regarding it as necessary in all cases where disease was less advanced, and he was sure the Society would be glad to hear the opinions of men with such practical experience as Dr. Barnes and Dr. Routh.—Dr. **Aveling** thought that the operation of Cæsarean section would not be justifiable if only one lip of the uterus were involved.—Dr. **Rogers** stated that in thirty-five years only two cases of this nature had occurred. The question of Cæsarean section was one of much importance.—Dr. **Barnes**, in reference to Dr. Meadows's assumption, that if all the cases were analysed, it would be found that the results would be as in those observed by himself, replied that this analysis had not been made, and it was not safe to frame a general law upon an assumption. The best plan at present was to consider each case as it came before us on its individual merits. In cases where the disease was of small extent it might be safer to let delivery take place in the ordinary way. Speaking from memory, he thought Dr. Oldham had published in the Guy's Reports cases which showed that it was better to take this course—i.e., not to induce labour, but to let pregnancy go on to term, and then to act according to indications.—Dr. Routh stated that in the cases he had seen it was impossible to deliver except by craniotomy.—Dr. Edis explained that he brought forward the present case, not with the view of advocating similar treatment in all cases—each case required to be treated on its own merits,—but as an instance of delivery *per vias naturales* where the disease was very extensive. Nature herself took the initiative, and seemed to indicate that delivery was possible, and for this reason Cæsarean section was not resorted to.

Dr. Alfred Meadows read a note "On the Post-mortem Diagnosis of a Nulliparous Uterus." Referring to the now celebrated trial of the brothers Wainwright for murder, he remarked on the extreme importance of being able to diagnose post mortem whether or not a uterus had ever borne a child, and on this point he invited the opinion and experience of the Society. In the case referred to he thought it was probably not too much to say that, if any absolute test existed whereby a positive opinion in the negative could have been given, the whole case for the prosecution must have failed on the first indictment, for it was well known that the person alleged to have been murdered had borne children. He, however, knew of no such test, nor did he think it could be affirmed, on the contrary, that this uterus had ever been gravid so far as appearances went. The thinness of the uterine walls, which in this case barely exceeded a quarter of an inch, and the distinctly convex shape of the internal aspect of the uterine walls, urged him to the opinion that this was a nulliparous uterus. Accordingly, the evidence which he gave at the recent trial was to the following effect—first, that, as a general rule, no absolutely certain opinion can be given by post-mortem examination only, even under the most favourable circumstances, on the question whether or not a woman had borne a child; secondly, that, on the question of probability, some reliance may be placed on the internal appearance of the uterine walls, especially with reference to their convexity; thirdly, that, so far as this particular uterus was concerned, there was certainly no proof that it had borne a child, but that, on the contrary, the evidence, doubtful and unreliable as it was, tended rather in the opposite direction, and justified an expression of opinion to that effect. The author then referred to a very delicate question of a medico-ethical character—viz., as to whether a scientific witness is at liberty to allow his private judgment on the general merits of a case to influence his opinion on a purely scientific question. Upon this point also he invited the opinion of the Society.—Dr. Edis inquired whether any notice had been taken of the condition of the ovaries. He thought some inference might have been drawn from their appearance.—Dr. Palfrey wished the discussion to be postponed, as he was collecting statistics bearing upon the subject. He had taught and been taught that the condition of the cervix was some guide as to previous pregnancy or not, but he was rather inclined to believe that the condition of the os was not so clear in deciding the question. It was far too important a matter to be discussed in a few minutes. He therefore proposed an adjournment.—Dr. Aveling suggested that the presence of a large polypus or other morbid growth in the uterus would modify the condition of the cervix.—Dr. Barnes seconded the proposal to adjourn the discussion upon the scientific question as to the evidences of pregnancy, but he wished to express his satisfaction at the course taken by Dr. Meadows in laying a formal statement of his views before his professional brethren, in a form that would be understood and appreciated, instead of trusting to the garbled reports of newspapers, and the distortions to which scientific evidence is liable under the manipulation of counsel.

The discussion was then adjourned to a future meeting.

Dr. Heywood Smith narrated the particulars of a case of Premature Labour at the seventh month, where rupture occurred, and the patient recovered. The case was complicated by placenta previa, and turning was resorted to. In similar cases he thought it important to keep the patient lying in such a position as that the uterus should be above the seat of the rupture, and to administer opium for the first forty-eight hours.

Dr. Wiltshire also narrated a case of Spontaneous Rupture of the Vagina with recovery. The promontory of the sacrum projected more than usual. The head, with the right leg, right arm, and funis, presented. The laceration was transverse at the junction of the vagina with the cervix uteri, and extended into the peritoneal cavity. Intestines were felt, but none prolapsed. Delivery was safely effected by turning, and the patient made an excellent recovery. The paper concluded with remarks on the nature, causation, and treatment of the accident.—Dr. Barnes wished to state his objection to accept in its absolute sense the doctrine that the uterus never ruptured unless its tissue was diseased. He himself had seen cases where no disease could be detected. He might distrust his own competency as an observer, but he had submitted specimens of one case to examination by Drs. Bristowe and Montgomery, who confirmed his observation. The conditions under which the uterus sometimes burst were quite compatible with the hypothesis of normal structure. Sudden violent contraction of the uterus upon fluid contents would, as in the case of the Florentine experiment of hydrostatic pressure inside a golden globe, cause rupture, unless the fluid escaped by a natural opening.—Dr. Palfrey had met with cases. He objected to the use of the syringe in these cases. In one instance immediate collapse had occurred in consequence; nothing would induce him to sanction it again. The irrigator answered every purpose where it was necessary to wash out the vagina. If the rupture favoured prolapse of the intestine he advocated sutures.—Dr. Edis referred to a case where turning and attempt at extraction had been resorted to in a primipara, the antero-posterior diameter of the pelvis being less than two inches. After prolonged efforts the body was extracted, the head being left behind. When Dr. Edis examined the patient, the hand passed readily through a large rupture in the upper part of the vagina and neck of the uterus into the peritoneal cavity, the head of the fœtus lying close under the liver. The patient died. He mentioned the case as illustrating the necessity of carefully determining, on first examination, the exact condition of the pelvis.—Dr. Barnes inquired if, in Dr. Wiltshire's case, the child was dead before rupture took place, because death of a child was often a cause of rupture.—Dr. Wiltshire replied that the funis had ceased to pulsate before the rupture. The patient had been kept on her back to prevent the descent of intestine.

Dr. J. W. J. Oswald communicated the particulars of a case of Cæsarean Section, where the pelvis was very deformed from rickets. The patient died on the fourth day. The antero-posterior diameter of the pelvis was only three-quarters of an inch.

West Kent Medico-Chirurgical Society.—The third meeting of the Society was held on Friday, Dec. 3rd, at the Royal Kent Dispensary, Greenwich-road, Dr. Prior Purvis (in the unavoidable absence of the President, Mr. J. N. Miller) in the chair. Dr. Tilbury Fox's paper on Ringworm was, in his absence, postponed until Friday, Feb. 4th, 1876. Mr. E. J. B. Burroughs, jun., Secretary, brought before the Members a very typical case of Congenital Syphilis treated by Mercurial Inunction. Mr. J. B. Saundry showed a very fine specimen of Gelatinous Polypus removed from the right nares of a woman during the week. The remainder of the evening was spent in a discussion on Syphilis and its Treatment, in which most of the members took part, illustrating their remarks by appropriate cases. Dr. Peacock will read a paper on Friday, Jan. 7th, 1876. Dr. J. C. Thorowgood was balloted for and unanimously elected an honorary member of the Society.

Bequests, &c., to Medical Charities.—Mr. James Houghton bequeathed £5000 to the Royal Southern Hospital, £500 to the Royal Infirmary, £250 to the North and South Dispensaries, and £100 to the Medical Mission, all at Liverpool. Sir Charles Pressley, K.C.B., has given £1000, Mr. Henry Thompson £500, and Mr. William Gue £163, towards the building fund of the proposed Cottage Infirmary at Andover.

POST-MORTEM EXAMINATION OF THE REMAINS OF HARRIET LANE.

A Clinical Lecture, delivered at Westminster Hospital,

BY THOMAS BOND, F.R.C.S., B.S. LOND.,
ASSISTANT-SURGEON TO THE HOSPITAL AND LECTURER ON FORENSIC MEDICINE.

(*Concluded from p.* 842.)

HAVING given you, gentlemen, all the details connected with the post-mortem, I now proceed to comment on them.

The remains were those of a woman, for the reasons I have already given. I was able to state she had been dead for many months, because of the great dryness and mummification of certain parts, and from the decay and decomposition of other parts, also by the formation of adipocere. On the other hand, I was able to state with certainty that she had not been dead for years, because the muscular tissue was well preserved, the cut portions being moist, flaccid, and pale-red. The articular ends of the bones also were covered with cartilage in perfect preservation, and the cancellous tissue of the bones was still moist and of a reddish colour. I therefore stated confidently that the appearances were consistent with what I should expect to find in a body that had been buried twelve months; but I could not say that the remains of this particular body had not been buried six months less or six months more than that period.

Next comes the important inquiry, What was the cause of death? Could it have been from natural causes? Yes, it might be possible, but only on the supposition that two bullets were fired into the brain so quickly after death that bleeding to a very considerable extent ensued. Now, it is very difficult to say how much blood may escape after death, and after what period it will flow. Of course it mainly depends on the nature of the wound and the part injured. A cut throat might bleed a good deal after a period of death at which a bullet-wound would not bleed at all. It is, however, absurd to imagine that a woman would be shot so immediately after natural death that infiltration of blood into the tissues might occur; so I came to the conclusion readily that one of the pistol-shots had caused death. I am of opinion that the first shot described was the fatal one, because in the track of that bullet I found blood inside the skull, and infiltrated under the scalp, although no large vessel was injured. I may here observe that whenever I speak of having found blood I am not merely guessing that it was so. I examined each portion I suspected to be blood with the microscope, and invariably succeeded in finding well-marked blood-corpuscles. I did not succeed in crystallising hæmin, although during the process I constantly found that the edges of the acetate of soda crystals, which are formed in the process, were tinged dark-red, exactly the colour of hæmin. I tried the colour tests, but did not get any result, nor is it to be wondered at, considering how much the blood was mixed with lime and grease. Indeed I did not expect to find such characteristic blood-corpuscles, but there is no doubt they were found, as Mr. Larkin's observations, made independently of mine, were confirmatory. My colleague, Dr. Dupré, also confirmed my observations.

Having satisfied myself that death was caused by the pistol-shots, it was next incumbent on me to say whether they were suicidal or homicidal. You may observe that in speaking of the cause of death I have left out the question of the cut throat altogether. My reason you have already heard—viz., because I could not say positively when that cut was made. My evidence went to prove, however, that it was not suicidal—firstly, because of the depth, the cut going nearly through the body and transverse process of the third cervical vertebra; secondly, because of the direction, from the front upwards and backwards, commencing superficially and then going deeply under the angle of the jaw on the left side. The defence set up the theory of suicide by pistol-shots, and assumed that the cut in the throat was done during dismemberment. It has been stated that the counsel for the defence urged "that it might be possible for a person with two bullets in the brain to inflict a suicidal wound in the throat." This is an error. In my opinion the learned judge also erred in saying "the concussion of the third bullet which lodged in the pad was probably sufficient to produce insensibility." It is very improbable that a small body like a bullet, weighing a little over a drachm, when stopped by an elastic and bulky medium like a pad and hairpins, would communicate its force directly through to the parts underneath. The example of a man being able to bear without inconvenience a large stone on his chest while it is being broken by a hammer, is a proof of the contrary. Mr. Larkin was asked a most pertinent question—viz., "What would be the state of the sensibility after firing one of the bullets into the brain?" He answered that he had not sufficient experience of gunshot wounds to say. I would have given a different answer—viz., that immediately the first bullet entered the head all co-ordinate action would be lost, rendering it impossible to fire another well-directed shot at the head. This fact and the further evidence that the third bullet was fired from behind into the pad, would render the theory of suicide absolutely untenable. Thus, there was no doubt that a murder had been committed.

The next point was the question of identity. This was to be determined by two sets of facts: first, the identity of ornaments and portions of wearing apparel found in the grave with those known to be Harriet Lane's; secondly, the anatomical observations and their correspondence with the description of Harriet Lane. The latter only concerned me, and of them the scar played the most important part.

I will now enumerate the separate points of identity and treat them in detail.

1. *Height.*—Harriet Lane was known to be about 5 ft. ½ in. tall. The measurement of the remains, carried out as I have described, was 4 ft. 11½ in., so there was exactly an inch discrepancy. This, considering the difficulty of fitting the parts accurately together, appeared to me very unimportant, but the counsel thought a good deal of it. It struck me at once that it might be due to shrinking of the intervertebral cartilages. I remembered dissecting the spine of an Egyptian mummy while a prosector at the College of Surgeons, and noticing the dried and shrunken intervertebral discs. I therefore cut out one of the intervertebral cartilages from the remains, and found it perceptibly harder and drier than in a recent subject. Again, the scalp and the skin and fat covering the heels were exceedingly dry and shrunken, so that it was quite possible to account for the discrepancy between the two measurements.

2. *Age.*—Harriet Lane's age was twenty-four, and from my previous description you will see at once that such an age was perfectly compatible with the appearances of the remains. The articular cartilages were thick, the cancellous tissue in the bones abundant, and the epiphyses about the shoulder, thigh, and knee joints were all united. The facts were communicated to the Treasury solicitor, but no questions on these points were asked, and it is not a wise plan to volunteer evidence during examination which is not of a conclusive character, as it might be used either way; the evidence would have proved the woman to be over twenty, but it would equally have proved her to be over thirty. The counsel for the prosecution very wisely was content to bring prominently forward the most obvious and reliable reason for my opinion that the age was from twenty to twenty-five—viz., that the wisdom tooth of the left upper jaw was uncut, while all the rest had come through.

3. *General shape.*—Harriet Lane was known to be thin and slender. The hands and feet of the remains were remarkably thin, much more so than could be accounted for by any drying of the tissues; the bones were likewise light and small, and the whole frame was of slender build.

4. *Teeth.*—It was proved that Harriet Lane had the first bicuspid tooth in the left upper jaw decayed, but that all the rest were sound and good, also that the two front teeth were slightly prominent. Mr. Aubin noticed the prominence of the teeth before he heard the evidence. There was likewise found the decayed tooth, as described by the witnesses who had no means of knowing what I had found. Some of the teeth had dropped out. It had evidently occurred after death, as they fitted perfectly and were all put back except the right upper and left lower central incisors.

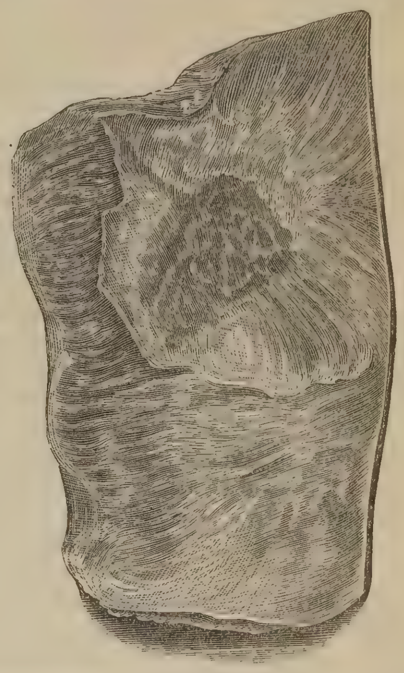
5. *Hair.*—The hair of Harriet Lane was of a light auburn colour. It was curled and tied with a piece of velvet, and fixed at the back to a peculiar pad with a quantity of

hairpins. The pad was found and recognised. The hairpins and velvet were also found attached. The hair was found to be generally light auburn, and in some parts curly. Where it was in contact with the hairpins it was dark-red, probably from oxidation of the iron in contact with it. The hair was very fine. Under the microscope it was seen to be coated freely with granular material; the cortical substance was transparent, the medullary portion was broken up into irregular granular masses. It was very brittle and broke easily; the fractured ends could be seen sharply defined under the microscope. All the hair I examined—namely, that taken from the grave, the spade, the hatchet, and the body—corresponded perfectly in size, colour, texture, dryness, and granular covering. The question as to the effect of chloride of lime on the hair was asked of each medical witness, but we none of us could give any very definite opinions. I believe it could have had very little effect, as it is not a very easy matter to bleach even dark hair with chlorine, the hair having to be prepared, and the washing with chlorine having to be constantly repeated to be effectual.

6. *Feet and fingers.*—A boot of Harriet Lane's was produced which had evidently been worn on a rather long and slender foot. The boot measured nine inches extreme length, the feet on the remains measured eight inches and a half, and could undoubtedly be got inside the boot. The fingers would easily go into the rings which were found, but there were no marks on the ring finger. It was proved that Harriet Lane seldom wore the rings, as they were generally in pawn.

7. *The uterus.*—The condition of this organ was made much more of than its importance deserved. It is quite impossible to state with certainty that a uterus has been impregnated, as certain diseases in the virgin uterus might cause the post-mortem appearances to resemble in every respect that of an impregnated uterus. In this case it was found much decomposed and shrunken, as I have described to you. After soaking in spirit-and-water it enlarged to three times its former size; the texture became tougher, but the walls remained exceedingly relaxed and flaccid. It was both longer and broader than a virgin uterus is usually found. The os was transverse, and the neck protruded very little into the vagina. The walls were thin compared with the size of the cavity. In shape it was somewhat triangular, but was altogether in such a flaccid condition that very little reliance could be placed on its form. The strongest evidence I could give was, that my opinion inclined to the view that it had borne children, but it was quite sufficient for me to prove that the appearances were not inconsistent with child-bearing, and no one could controvert this.*

8. *The scar.*—This was the last and most important link in the chain of evidence supporting identification. I only found it while present with Mr. Aubin, who was examining the remains in the interests of the prisoner. I made one examination and one report only to the Treasury; the three subsequent examinations were made by request of and by appointment with Mr. Aubin. It had been stated by Mr. Lane that his daughter had a scar on one of her legs, but he could not recollect the position, or on which one. I therefore scraped away very carefully the chloride of lime and earth which thickly covered most of the body. I first examined the left leg, but discovered nothing excepting the dried patches on the skin which I have previously described, and one of which Mr. Aubin cut out subsequently, under the impression that it was a scar. On scraping the right leg, I found a scar exactly over the fibula, about four inches below the point of the knee. Mr. T. Allchin, a brother of my colleague, Dr. Allchin, has executed a most faithful drawing of the scar, which shows its character perfectly. The central portion was about the size of a shilling, rather elongated downwards and backwards. It was hard and fibrous, and one-eighth of an inch in depth. In front the skin was healthy, but much puckered; at the back it was white and smooth, similar to the appearance caused by the scar of a burn or scald, and extended nearly an inch beyond the fibrous portion. On finding this scar, Mr. Aubin, Mr. Larkin, and I agreed to inform no one of its position or character. The counsel for the prosecution was informed only that there was a scar, and he cross-examined all the witnesses separately, in perfect ignorance himself as to its locality or character. Each of the witnesses described in detail the appearances and exact position of the scar as I found it. This, gentlemen, I consider, would of itself have gone far to prove the identity of the remains with the body of Harriet Lane; but taken in conjunction with the other anatomical similarities, it makes one of the best-established cases on record of identity proved by medical evidence.



ROYAL COLLEGE OF PHYSICIANS.

AT a meeting of the College of Physicians held on Monday, Dr. Risdon Bennett was appointed to represent the College in conjunction with Dr. Pitman, and in place of Sir George Burrows, the President, prevented by illness from so doing, at the conference appointed to be held, at the request of the College of Surgeons, in reference to certain proposed alterations in the "Conjoint Scheme" for an examining board for England.

A report was brought up from the Leprosy Committee as a reply to a communication received from Lord Carnarvon, in which the College was requested to state whether the facts recently cited in a paper on Leprosy published in the *British and Foreign Medico-Chirurgical Review* were such as to incline the College to modify its already expressed opinion in reference to the contagiousness of the disease. The College, adopting the report, declared, notwithstanding the facts brought forward by the writer, that its opinion remained unaltered.

A report was also received from the Committee appointed to inquire into the Regulations of the College on the use of the title of "Doctor" by persons not being graduates in Medicine of a University. The discussion of this report was deferred till the next College meeting. The gist of the report was a recommendation that the present bye-law on the subject should be abrogated—that no fellow, member, or licentiate should be allowed to append M.D., or any initial letters signifying the same, unless he has obtained the degree from a body qualified to confer it; but that in all official documents or communications all fellows and members *might* be styled by the courtesy title of "Doctor." The report is likely to give rise to much discussion.

---

* Mr. Larkin soaked portions of the abdominal walls, and found distinct traces of the lineæ albicantes.

THE LANCET.

LONDON: SATURDAY, DECEMBER 25, 1875.

It is difficult to confine within reasonable limits a summary of the history of Medicine even for a year. It includes, or may be made to include, so much. From a new result of the action of phosphorus to a new consequence of the action of passion; from the journey of a Prince through India to the procession of a group of hardy discoverers to the regions of the North Pole,—almost everything that happens nowadays may be shown to have medical interest. Medicine being no longer a mere curative art and "mystery" contemplating the recovery of a "few sick folk," but a science—taking cognisance of all the influences that conserve human life and health, severe in its methods, stern in its conclusions, inviting the criticism of men of science, and compelling the attention of statesmen,—it covers a field of inquiry of great variety and extent. It turns up everywhere—in laboratories and law courts, in State departments and in the hovels of the poor, in universities and in schools. In its larger scope it involves questions in sociology, in engineering, in meteorology, in legislation. It is the most human of all the sciences. It respects the epidemic that constitutes a national disaster, and the individual illness that gives anxiety to a family. The history of Medicine in the year that is now closing amply justifies the description we have given, as will appear in our summary. Briefly, the year may be said to have been remarkable, and not very friendly to life. The cold of the early part of it, and of the closing weeks of the previous year, affected very unfavourably the public health. In the week ending the 9th of January no less than 2296 deaths were registered. A long frost disappeared on Friday, Jan. 21st, after twenty-four days with an average temperature of 31° F., or 7·9 below the average for the corresponding week in fifty years. The cold continued to prevail far into the year, delaying the advent of summer. One of the most remarkable features of the year has been the floods which have occurred in this country and in various countries of the Continent, especially France, entailing direct loss of life, enormous inconvenience, and ulterior medical consequences which have yet to be described. It is probable that the mortality of the year, taken as a whole, will compare unfavourably with that of most years. As a consequence, medical practice has been arduous and laborious.

There has been no lack of interest taken, or diminution of activity displayed, in the proceedings of the Medical Societies during the past year. Their meetings have been most numerously attended; and the quantity of material provided has been, in most cases, more than sufficient to supply the wants of the meeting. The customary debate at the Pathological Society took place in the spring, when many nights were devoted to the question of the Germ Theory of Disease. The discussion was opened by Dr. Bastian in an exhaustive review of the whole subject, with the object of showing that the germ theory was inadequate to account for facts of contagious and epidemic diseases. He was immediately followed by Dr. Sanderson, who, however, did not enter into controversy, but contented himself with deprecating any discussion as premature. On the whole, the outcome of the debate was unsatisfactory; for the chief upholders of the theory attacked by Dr. Bastian were either timorously reticent or indifferent in the cause they had at heart. The example set by the Pathological Society was followed at the Obstetrical Society, where the subject of Puerperal Fever was debated for many months. The subject was introduced by Mr. Spencer Wells, who preferred to lay before the meeting a series of questions to be answered, rather than to commit himself to any dogmatic statements; and although the debate was enriched by the utterances of such leaders in the obstetrical world as Drs. Fordyce Barker, Arthur Farre, Barnes, and Braxton Hicks, the questions still remained open when the discussion closed. The growing tendency to discuss at length matters of pathological and therapeutical import has shown itself since the summer recess both in the Royal Medical and Chirurgical Society and in the Clinical Society. In the former, a historical review of Croup and Diphtheria, by Dr. Semple—with the object of showing the identity of the two affections,—led to a brief but instructive debate, in which Sir William Jenner, Dr. West, and Dr. Dickinson took part; with the result that a recommendation was forwarded to the Council of the Society to consider the expediency of appointing a committee to investigate this question. It will be remembered that the subject was brought to the front in our columns at the commencement of the year, and also debated at the Clinical Society on the occasion of a paper read by Mr. R. W. Parker, on a case of Scald of the Glottis. At the last-named Society, also, a brief and incomplete discussion on Antiseptic Surgery occupied one of the first meetings after the recess; a debate, however, which only served to show a want of sufficient appreciation of Mr. Lister's method and the desirability of its being more fully discussed. Turning now to the various papers read before these bodies, we may note many that will have a permanent value, and which show a distinct advance in medicine and surgery. At the Royal Medical and Chirurgical Society one of the largest meetings of the year was held on the occasion of the reading of a paper by the late Mr. Acton, on the Prevalence and Severity of Syphilis in the Army, with especial reference to the operation of the Contagious Diseases Acts; the opponents of these measures being represented by Drs. Birkbeck Nevins and Drysdale. Mr. Rivington communicated a remarkable case of Pulsating Tumour of the Orbit; Dr. Dickinson, a valuable contribution to the Pathology of Chorea, based on no fewer than seven post-mortem examinations. More recent, and still fresh in the memory of our readers, have been the papers on Aortic Aneurism in the Army, by Mr. F. J. Welch; and on Abdominal Section for Intussusception, by Mr. Marsh, Dr. Fagge and Mr. Howse, and Mr. Hutchinson, to whom indeed is due the credit of having been the first to draw attention to the feasibility of the operation. The Clinical Society was fortunate in hearing from its newly-elected President, Sir Wm. Jenner, an able address, dealing chiefly with the Etiology of Typhoid Fever; and among the notable papers of the year may be included one by Dr. Vivian Poore, on a case of Palsy of the Serratus Magnus; one on an unprecedented case of High Temperature following Injury to the Spine, by Mr. J. Teale; a report on Hydroa, by Mr. Hutchinson; and a case of Lymphadenoma, by Mr. W. Haward. At the Pathological Society a very large number of specimens have been exhibited, many of great interest and importance, which it would be impossible to enumerate here. Mr. Hutchinson's contribution on the kind of Teeth usually met with in Zonular Cataract deserves, however, special notice, as an illustration of careful clinical observation. At the Medical Society the Lettsomian Lectures were delivered by Mr. Maunder, who chose for his subject the Surgery of the Arteries. These lectures were fully reported in our columns, and proved a valuable contribution to surgical literature. Beyond the debate on Puerperal Fever, there has been nothing very worthy of note at the Obstetrical Society, which continues to be one of the most popular and practical of these assemblies. The institution of a course of lectures to be annually delivered before the Harveian Society will mark the year of Dr. Broadbent's presidency, and serve to indicate a growing activity in this body. The lecturer for this year was Dr. Sibson, who gave a full account of his observations upon Arterial Tension in Bright's Disease, with especial reference to the treatment of that disorder. On the whole, the past year has been a prosperous one with the Societies; and the amount of good work done by them shows that they still maintain the traditions of the past, as it is an earnest of what may be expected from them in the future.

The College of Physicians has passed through a somewhat uneventful year. Sir George Burrows was honoured by re-election for the fifth time to the chair of the College, on which occasion he delivered an animated address on Conjoint Schemes, physicians' fees, &c. The lectures of the College were very able. The Croonian Lectures by Dr. E. Headlam Greenhow constitute perhaps the most perfect statement extant of the state of our knowledge of Addison's disease. In the Gulstonian Lectures Dr. R. J. Lee discussed the urgent questions involved in puerperal fever. In the Lumleian Lectures Dr. Lionel Beale vindicated with characteristic earnestness his well-known views as to the absolute difference between vital action and action in non-living matter. According to a Return from the College to the General Medical Council, the number which passed its final examination for the licence last year was eighty-five. The licence is a double qualification, the only double qualification granted by a single body.

A review of the transactions of the Council of the Royal College of Surgeons of England during the past year affords satisfactory evidence that that body has been aroused to a sense of the duty it owes to the profession at large, and to its own fellows and members in particular. Since the close of last year many sound and radical reforms have been introduced. An Act of Parliament has been obtained to enable the College to join with other licensing bodies in conducting what is known as the "Conjoint Examination"—the one-portal into the ranks of the medical profession; and within the last few weeks the President of the College has issued an invitation to all the co-operating bodies to a conference to discuss the scheme. This conference has been held, but no final decision has been come to. What will be the ultimate issue of this last attempt to organise the Conjoint Scheme we cannot yet say; but the fact that the matter has been taken in hand by Sir James Paget, the present President, is very good evidence that it will be seriously considered, and not lightly laid on one side. If this endeavour prove unsuccessful, all hope of voluntary and amicable co-operation of the licensing bodies may be looked upon as lost. But although the College may find itself unable or unwilling to yield to the demands made upon it by the other co-operating bodies, the events of the past year are sufficient to show that the College may rise to a high and honourable career, and command the confidence and respect of all. It has at last been resolved to separate the examiners in Anatomy and Physiology from those in Surgery and Surgical Pathology; and this week the special examiners in Anatomy were appointed, and they will commence their duties at the January examinations. It is needless to observe that if the selection of the candidates for the post of examiners has been wisely made, and we think it has, the examinational tests at the College will in future possess a higher value and a more uniform character than they have hitherto had. Several things yet remain to be done to make the anatomical and physiological examinations at the College all that it is desirable they should be. The time devoted to examining the candidates should be extended, the system of marking should be altered, and what is of equal importance is that special examiners in Physiology should be appointed, and a special examination held. Respecting the anatomical examinations of the College, it is worthy of remark that Mr. John Marshall lately laid before the Council a scheme to institute a compulsory elementary examination in Anatomy at the end of the first year. Although this proposal appeared at first sight highly commendable, we felt bound, in the interests of medical education, to oppose it for reasons which we gave at length a few weeks ago. The changes that have been made in the constitution of the Court of Examiners will make themselves felt as much at the Pass Examination as at the Primary. During the year the Court of Examiners has been strengthened by the appointment of two surgeons of high repute and standing. Early in the year, Mr. John Cooper Forster, of Guy's Hospital, was elected an examiner in place of Mr. Hilton; and more recently, at the request of many influential members of the Council, Mr. Erichsen, of University College, accepted an examinership, on the distinct understanding that the separation of examiners should be at once effected, and that he should not be called upon to examine in anything but Surgery. It is scarcely possible to exaggerate the influence that these appointments will have on the value of the College diplomas. The Court of Examiners, with one or two exceptions, is now therefore made up of the very best surgeons in London, most of whom have enjoyed unusually large opportunities as teachers and examiners. The election of members to the Council was a spirited one, and attended with the happiest results. The three retiring candidates were Mr. Prescott Hewett, Mr. Birkett, and Mr. Spencer

Smith. All were candidates for re-election; but Mr. Cooper Forster successfully contested the election with Mr. Smith, who was defeated by a large number of votes, although he had polled an unusually large proportion of "plumpers." Two other important matters have occurred this year. In accordance with a proposition of Mr. Marshall, Mr. Le Gros Clark, the President at the time, presented to the Fellows of the College the first annual report of the transactions of the Council for the year. Lastly, Mr. Brudenell Carter, ophthalmic surgeon to St. George's Hospital, was appointed Hunterian Professor of Surgery, with the understanding that he should deliver a course of lectures on ophthalmological subjects. This appointment met with the approval of the Council, although the two Hunterian professors immediately preceding Mr. Carter were also surgeons at St. George's Hospital.

In the region of Medical Therapeutics it is not easy to give precise statements of the progress that is undoubtedly made from year to year. The reduction of dangerously high temperatures by cold water, variously used, continues to receive illustration. Our own columns have been the medium through which several cases of the kind have been made public; and in various articles we have expounded the success of continental physicians; particularly, in a recent number, we have directed attention to Professor Liebermeister's article on Typhoid Fever in the Cyclopædia of Medicine. The efficacy of ergot in cases of hæmoptysis was recently shown in a paper by Dr. James Williamson, of the Hospital for Consumption, Ventnor, detailing its effects in fifty cases. Dr. Wilson Fox reported in our columns, in July, the remarkable cure of a case of leukhæmia splenica by phosphorus; following, in this successful treatment, the example of Dr. Broadbent in a case reported in the January number of the *Practitioner*. Two cases of strychnine poisoning have been successfully treated, one with chloral and the other with chloroform. In the Radcliffe Infirmary, Oxford, under the care of Dr. Acland, a case of unilateral convulsions in a child was successfully treated by chloral, after the failure of iodide of potassium, belladonna, and other remedies. The chloride of ammonium was found very successful in the treatment of hæmatinuria, by Dr. Warburton Begbie. Dr. Johnston, of Shanghai, speaks very highly of the subcutaneous injection of atropine in opium-poisoning, in which his experience has been very large. We may note the experience of Dr. Spencer Thomson on the efficacy of Gelseminum sempervirens, or yellow jasmine, for the rapid relief of neuralgic pain; and that of Surgeon-Major Watson of boracic acid, as an application in ringworm.

It is with great pleasure that we hear the Physiological School of Cambridge, under the master-hand of Dr. Foster, one of the most able and energetic of the younger generation of physiologists, and who has thrown himself heart and soul into the good work, is thriving exceedingly. The teaching in practical physiology is here so good that it will soon be no longer necessary for a student to seek such instruction on the Continent, and we may hope, indeed, that some day the tide will turn, and French and Germans alike be attracted to our ancient universities for the best and most advanced physiological instruction.

The report of the Vivisection Committee has not as yet been published, but there is every reason to believe that it will result in the establishment of vivisection as a necessary means for the advancement of knowledge, when undertaken by competent men for definite objects, and with the avoidance of all unnecessary pain.

Although no startling discoveries have been announced during the year in the domain of Surgery, a retrospect of the literature of the period affords sufficient evidence that many investigators have been diligently pursuing their labours, and making important additions to the stores of surgical knowledge. Much valuable work has been done in the surgery of the vascular system. We may refer especially to Mr. Holmes's elaborate lectures on Popliteal Aneurism, and Mr. Maunder's Lettsomian Lectures on the Surgery of the Arteries, both of which were reported at length in our columns. Mr. Annandale, of Edinburgh, has successfully treated a case of traumatic popliteal aneurism by tying the popliteal artery and vein, and Staff-surgeon Walter Reid cured a case of popliteal aneurism by the application of Esmarch's bandage for fifty minutes. Mr. Frederick Ensor, of South Africa, ligatured simultaneously the right common carotid and subclavian artery for aneurism of the aorta and innominate artery. The patient did well for many weeks, but caught a severe cold by sitting in a cold room with only a night-shirt on him. Pleurisy supervened, and the patient died comatose on the sixty-fifth day after operation. Mr. John Gay has recorded a case of aneurism of the dorsum of the tongue, and a rare case of aneurismal tumour in the pharynx was recently recorded by Mr. John J. Barnes. Early in the year Mr. Marshall, of University College Hospital, published an interesting case of varicose veins cured by the removal of the trunk of the vein by dissection. In this case Esmarch's bandage was used to facilitate the operation, and the wound was subsequently dressed antiseptically. Mr. Callender effectually cured persistent neuralgia in a stump by dissecting out the end of the nerve, and stretching it. Mr. James F. West, of Birmingham, has had under his care a remarkable case of meningocele with spina bifida, and Mr. J. W. Dove has put upon record a case in which an iron staple weighing four drachms five grains was fixed in the œsophagus for more than six weeks. A valuable essay by Mr. Teale appeared in our columns insisting on the advantages of exploring the abdominal cavity in extreme cases of obstruction of the bowel in which the seat of obstruction is unknown. Mr. Hutchinson successfully performed abdominal section for intussusception in a child two years of age. Sir Henry Thompson has made some important and valuable contributions to our knowledge of stone in the bladder and of the value of lithotrity as a means of removing vesical calculus. In the early part of the year Sir Henry published the results of one hundred consecutive cases of stone in the bladder, the majority of which were treated by the crushing operation; and later on, in answer to a suggestion from Mr. Thomas Smith, he recorded the results of his inquiry into the condition of fifty-one of these cases of lithotrity in elderly adults, at periods varying from one to two years after operation. This careful and painstaking inquiry furnished overwhelming evidence of the great value of lithotrity in properly selected cases, and set at rest the doubts that had been very widely entertained respecting the ultimate value of the operation and of its advantages over lithotomy. It is interesting in this connexion to mention a series of thirteen consecutive cases of lithotomy, extending over twenty months, all ending in cure, by Mr. GEORGE HEATH, of Newcastle-on-Tyne, reported in our columns in June. Quite recently we have published some lectures delivered by Sir HENRY THOMPSON at University College Hospital, on urinary diseases. In these lectures a vigorous and well-timed onslaught was made on the purely mechanical treatment of urethral strictures, a treatment which Sir HENRY has shown to be founded on erroneous notions respecting the structure and calibre of the urethra. It is needless to say that within the limits of this condemnation the much-vaunted plan of OTIS was comprised. Mr. HENRY SMITH has recorded his later experience, which continues as favourable as ever, of the treatment of hæmorrhoids and prolapsus of the rectum by the clamp and cautery. The antiseptic system has come in for a large share of attention. Through the valuable papers published by Mr. LISTER in our columns, on the recent improvement in the details of this system, and through Mr. LISTER's demonstration of his method at the British Medical Association and at the Clinical Society, the subject has been brought very prominently forward. Bearing on the question of treating wounds, Mr. JONATHAN HUTCHINSON has described what he terms an antiphlogistic method of dressing operation wounds. This consists of applying over the wound a lotion composed of solution of lead with rectified spirits and water. Mr. HUTCHINSON speaks very favourably of this method, as tending to promote union by first intention.

We have been at no small pains to maintain the character of the "Mirror of Hospital Practice" as a repertory of interesting medical and surgical experience, special care having been taken to ensure accuracy of the records. It would be ungracious if we did not take this opportunity of expressing our indebtedness to the courtesy of the physicians and surgeons at the various metropolitan and provincial hospitals who have allowed us free access to their wards and cases, and have furnished us with material, and to the patience and co-operation of those clerks and dressers who have supplied us with facts concerning the history and progress of the cases. In the "Mirror" we have endeavoured to lay before our readers the mode of practice adopted at the various medical schools, and to set forth the doctrines and opinions held by those who are entrusted with the education of students, and into whose hands the maintenance of the honour and dignity of the science and art of medicine and surgery has been largely confided. Every department of practical medicine and surgery has been represented, and in those cases that seemed to call for it, an attempt has been made to enhance the value of the records by prefixing or appending short comments or clinical remarks. A brief summary will suffice to show the nature of the reports. A long and carefully prepared series of cases of coxitis was recorded from the practice of Mr. HULKE, of Middlesex Hospital, illustrating the mode of treatment of this disease in its various stages, the great advantage of early treatment by fixing the joint and exercising traction on the thigh being particularly referred to. Last week we published a remarkable case of dry gangrene of both legs that is at present under the care of the same gentleman. A case of suppurating synovitis treated by aspiration, in which recovery took place with a movable joint was recorded from the practice of Mr. JONATHAN HUTCHINSON at the London Hospital. Two cases have also been recorded in which loose bodies were removed by free incision antiseptically from the knee-joint. In both cases—one under the care of Mr. JOSEPH BELL, of Edinburgh, the other under Dr. WILLIAMS, of Middlesborough—the patients recovered with perfectly movable joints. From University College Hospital we recorded a case under the care of Mr. MARSHALL, in which death took place nine days after a fracture of the atlas; and from Mr. HUTCHINSON's practice a remarkable case of fracture of the spinal column at the fifth cervical vertebra, in which the temperature fifteen hours after the accident was 92°, but which went up to 106·3° just before death, thirty-eight hours after the infliction of the injury. A remarkable case was published from St. George's Hospital. A man sixty-four years of age was admitted with a large chronic ulcer of the leg. Mr. PRESCOTT HEWETT planted six skin-grafts on the base of the ulcer. All the plants took well, and rapidly grew, until they became about the size of a shilling, when a very curious phenomenon was observed. Each of the grafts softened in the centre, which became slowly absorbed, until only six whitish rings were left. Notwithstanding this central absorption, the rings extended peripherally until they met, and gradually extended to the sides of the ulcer, where they were lost. The same result took place in a second set of grafts which were derived from another person. From the Bristol Royal Infirmary Mr. CHARLES STEELE sent the notes of a case of hydrocele situated in the abdomen caused by an undescended testicle. Dr. MACKEY, of the Children's Hospital, Birmingham, supplied us with the notes of a case of intussusception of the bowel in a child. Although the case terminated fatally, and no operation was performed on account of the child being actually moribund when admitted into the hospital, the post-mortem examination showed that if the abdomen had been opened during life there would have been no difficulty in reducing the intussusception, as there was scarcely any inflammation, and the strangulation was not tight. From Mr. SYDNEY JONES's practice at St. Thomas's we published the notes of a case in which gastrostomy had been performed for cancerous stricture of the œsophagus. Unfortunately, the patient died on the fortieth day after the operation from bronchitis. The following are a few of the more interesting medical cases recorded in the "Mirror":—Acute Rheumatism, with carditis; administration of large quantities of alcohol (twenty-four ounces in twenty-four hours); recovery; under the care of Dr. WILSON FOX. Exophthalmic Goitre, associated with diabetes, under the care of Dr. WILKS; and a remarkable case of Iodism, in which tracheotomy was performed, under the care of Dr. FENWICK, of the London Hospital. Hæmorrhage into the Pons Varolii, under the care of Dr. CRICHTON BROWNE, of the West Riding Asylum. Lastly, notes on the Treatment of Syphilitic Headache and

Insomnia by small and frequently-repeated doses of Calomel, by Dr. Peter, of Paris.

In our Review columns we have striven to indicate what we considered the best sources of information, whether English, Continental, or American, to keep our readers *au courant* with the progress of scientific and literary work, giving the most prominent place to medical and surgical books. Without restricting ourselves exclusively to these, we have been enabled to introduce some variety into this branch of journalism. A considerable number of new works or of new editions of old works on anatomy and physiology have been published in the course of the year. Amongst the more important of these is the translation by Dr. Gamgee of the Elements of Human Physiology by Prof. Hermann, a work that is well adapted to form a text-book for advanced students, or as a foundation for lectures, but it is somewhat too condensed in style for beginners. It is, however, a thoroughly reliable book. Dr. A. E. Barker has done good service in rendering into very readable English the important work of Frey on the Histology and Histo-Chemistry of Man, a work containing much original research, and enriched with many illustrations. The same may be said of Messrs. Bennett and Thiselton Dyer's translation of Julius Sach's Text-book of Botany, the finest work that has appeared in this department of biology for many years past, and one that contains a large amount of material not readily accessible even to the professed botanist, arranged in excellent form. Dr. Amory has translated a small work on Physiology, by Küss, the talented Professor of Strasburg, too early lost to science, which, with some faults in the perspective of the subject, possesses much originality in its treatment. New editions have been published of the larger Human Physiology of Dr. Carpenter and of Dr. Dalton, both of which appear to be well worked up to the present state of physiological knowledge. Dr. Flint has completed his valuable Treatise on Physiology by the publication of the fifth volume. The eighth edition of Quain and Sharpey's Anatomy has been brought out under the editorship of Dr. Schafer. Amongst foreign works on this subject we may mention Brücke's Vorlesungen, or Lectures on Physiology, which proves somewhat disappointing, considering the high renown of the author as a teacher; Beauni's Nouveaux Elémens de Physiologie Humaine and Budge's Compendium de Physiologie Humaine, from a perusal of which those of our junior readers who may not happen to be very familiar with French, or who may be desirous of keeping up their knowledge of that language, will derive both pleasure and profit. The vigorous though heretical treatise of Ernest Haeckel, entitled the History of Creation, for some of the statements in which the book assuredly, and probably the author, would have been burnt a few centuries ago, has been translated by a lady and revised by Dr. Ray Lankester. In connexion with this may be mentioned, as having a similar tendency, the Doctrine of Descent and Darwinism, by Oscar Schmidt, which has been published in the semi-popular international series of Henry King. Both authors accept without the smallest reservation Darwin's views; Haeckel, indeed, regards him as the Newton of biology, everywhere speaking of him with the most profound reverence. A rather large work on Heredity, by Ribot, is, as is almost every work bearing, however remotely, on biology, strongly tinctured with, and perhaps it may be said, is even based on, the doctrine of Descent with modifications. Amongst the works devoted to special branches of biology we may refer to Dr. Klein's valuable investigations on the Lymphatic System and the histological characters of Sheep-pox, the last-named memoir furnishing sufficient evidence of how large a field is open to practised microscopists in supplying definite information on the etiology and pathology of ordinary processes of disease. Dr. Balfour has followed up the excellent work on Embryology he wrote in conjunction with Dr. Michael Foster by further researches on the Embryology of the Sharks, which contain the record of facts he has observed that have an important bearing on the mode of origin of the several tissues. Vulpian has published an excellent series of lectures on the Vaso-motor Apparatus. Some valuable memoirs on Anatomy and Comparative Anatomy have appeared in the three volumes of the "Encyclopædia Britannica" just issued, by Professors Huxley, Turner, M'Intosh, and others. A useful treatise on Elementary Biology has been issued by Professor Huxley and Dr. Martin of Cambridge, and a serviceable work on Practical Histology by Professor Rutherford, the object in both instances being to show how easy it is to follow in practice what appears at first sight difficult and unintelligible. Murchison's Functional Derangements of the Liver, Balthazar Foster's Clinical Medicine, Dr. Loomis's Lectures on Diseases of the Respiratory Organs, Heart, and Kidneys; the West Riding Lunatic Asylum Reports, edited by Dr. Crichton Brown; several important works, some of them Dictionaries, German and French, on Practical Medicine and Therapeutics; Dr. Dickinson's first part of Diseases of the Kidney and Urinary Derangements; Dr. Hayden's Diseases of the Heart and Aorta; Greenhow's Croonian Lectures on Addison's Disease; and last, but probably first in point of importance and utility, an English translation of Dr. H. von Ziemssen's Cyclopædia of Practical Medicine. In addition to several foreign encyclopædias and works on surgical subjects, Sir James Paget has given to the surgical world his experience in the shape of Clinical Lectures and Essays, Mr. Erichsen his experience on Concussion of the Spine and other obscure injuries of the Nervous System, and Surgeon-Major Porter his prize essay on the Best Treatment of Wounded in War. In Pathology and Morbid Anatomy we have had new editions of Dr. Wilks's admirable Lectures on Pathological Anatomy, edited by Dr. Walter Moxon; Jones and Sieveking's Manual, edited by Dr. Payne, and a third edition of Dr. T. Henry Green's capital little Introduction to the same subject. In Diseases of Women and Children the year saw the appearance of the fourth edition of Dr. Gaillard Thomas's very practical treatise, and the sixth edition of Dr. Churchill's work on the same subject; and, among other works on Midwifery, a second edition of Leishman's System has but recently appeared. In Ophthalmology, we would mention Mr. R. Brudenell Carter's Practical Treatise on Diseases of the Eye as a book written with a refreshing clearness of expression and directness of aim; and Macnamara's Manual has been translated into Bengali. ATTFIELD'S Chemistry, WATTS'S Dictionary of Chemistry and the Allied Branches, BRANDE'S Dictionary of Science, Literature, and Art, with some others of a similar character, have appeared; BROWN'S Manual of Botany, PERERIA'S Elements of Materia Medica and Therapeutics, abridged by BENTLEY and REDWOOD; the parts already published of Medicinal Plants by BENTLEY and TRIMEN; CAMERON'S Manual of Hygiene, and WEINHOLD'S very admirable Introduction to Experimental Physics have been favourably noticed in our columns. LUBBOCK'S Origin of Civilisation has reached a third edition; FRANCIS GALTON'S work on English Men of Science, their Nature and Nurture, is an interesting, very difficult, but, on the whole, disappointing study as elaborated by its author. Dr. TILBURY FOX has brought out several parts of an Illustrated Atlas of Skin Diseases, which promises to be of much general utility; and —— but it would be impossible to extend our notice, already beyond our limits, or proceed further with the list of books more or less noteworthy that have appeared in 1875.

Dr. MAUDSLEY has placed upon record a remarkable instance of a lunatic, who, upon two separate occasions, was apprehended and imprisoned for robbery. The unfortunate man was known to be the victim of general paralysis, and had been ordered to the seaside to be under the care of his wife. He escaped from her custody, and committed robbery in a railway carriage, and, being tried at Doncaster, was, in spite of the testimony of Dr. MAUDSLEY, Dr. CRICHTON BROWNE, and others, sentenced to imprisonment. On the urgent representation of his friends, however, he was liberated, but, owing to a strange laxity on the part of the authorities, he was not placed in safe custody, and within a few months he again escaped from his friends, again committed robbery, and again was apprehended by the police. He was then removed to the county asylum, and has since died.

The Judge of the Marylebone County Court, in the case of a disputed charge for medical attendance, has decided that three guineas per diem is not an excessive charge in cases where the attendance (by a general practitioner) is constant. The case in dispute was that of a child upon whom tracheotomy had been performed, and the practitioner was proved to have scarcely left his patient for 130 hours. The child recovered, mainly, as it was proved, through the unremitting attention of the practitioner, and a charge of seventeen guineas was made and readily allowed by the Judge.

There has been no remarkable case of poisoning during the year; but the death of Mrs. CHILDERS from an overdose of chloroform, which she administered to herself, has directed attention to the growing custom among sufferers of all kinds of indulging to a dangerous extent in the use of narcotic medicines. Chloral, chloroform, morphia, and hypodermic syringes seem to be about to take a recognised position on the toilet-table—a condition of things which cannot but become a source of much misery to those who are unable to bear up against a little pain or annoyances of other kinds.

Drunkenness, too, has occupied a good deal of the attention of the profession, and Mr. CARSTEN HOLTHOUSE has done good service in directing attention to the necessity of providing suitable homes and asylums for those who are the victims of dipsomania.

Mr. SEYMOUR HADEN, by a series of eloquent letters in *The Times*, has drawn public attention to the subject of burial. He proposes to do away with the expensive barbaric pomp which is even now still observable at many funerals, and to bury the dead immediately in the earth, without the intervention of impermeable coffins, which merely serve, as he justly points out, to retard the inevitable decomposition which must ensue.

An attempt has been made this year by the Government to redeem the pledge made to the country that sanitary legislation should be made one of its first objects. We say an attempt has been made because none of the measures brought forward have appeared to be earnest endeavours towards remedying the many evils against which they were specially directed. Still an advance has been made, and, thankful for small mercies, we must be glad that the steps taken have not been retrogressive. The boast, made by Mr. CROSS, that the sanitary work of the Government would be conceived and furthered with due regard to its gravity and complexity, is sadly at variance with his later utterance, that nearly all that can be done in the way of sanitary reform is to remove legal obstacles, and help the masses to help themselves. We need hardly remark that the passing of Acts of Parliament to facilitate the mere ordering of public and social affairs is not legislation. The most prominent, and, taken altogether, the most important measure of the Session was Mr. CROSS'S Bill for the improvement of artisans' dwellings. It is to be regretted that the Bill only took cognisance of towns—that is, towns of 25,000 inhabitants and upwards, while in rural districts landlords are still allowed to build houses, if they choose, in defiance of all the laws of hygiene. And, as the law at present stands, it is possible that, in the case of rapidly increasing towns, all buildings might be so badly constructed that when the number of inhabitants reached 25,000 the urban sanitary authority might be obliged to step in and order the destruction of the whole place. The Pollution of Rivers Bill, introduced by the Marquis of SALISBURY, met with such determined opposition in Committee that the Government resolved to withdraw it. This measure was altogether unsatisfactory, unjust, and mischievous: unsatisfactory because a larger and more comprehensive measure was expected; unjust because it dealt unequally with individual interests; and mischievous because it discouraged sanitary authorities from attempting to solve for themselves the problem of sewage disposal. The Sale of Food and Drugs Bill, introduced by Mr. SCLATER-BOOTH, was weakened by the number of exemptions introduced, which rendered the chances of escape of a fraudulent tradesman by no means few. Indeed, the fifth and sixth sections seem specially framed to enable the vendor to wriggle out of a conviction.

The preparation and successful carriage through Parliament of the Public Health Act, 1875, was the most notable work of the Local Government Board during the year on the sanitary side of the administration. By this Act the numerous Sanitary Acts then in operation were consolidated, and in some respects amended. The work of amendment was, however, quite subsidiary to the work of consolidation, and for the most part only carried so far as to remove certain defects impeding the operation of the existing law. By this consolidation of sanitary law certain great advantages have been obtained. First, it is no mean advantage practically to have the existing law within the compass of a single Act of Parliament, notwithstanding its bulkiness. But such evils as may attach to bulk have been in effect narrowed by the admirable arrangement of the Act. Next, the consolidation admits of the existing law being more readily studied, with reference to such further amendment as was required, as a whole. Although, from the nature of the subject, having now effected a consolidation, we must begin to tag to the consolidating Act a fringe of amending Acts, these need not be of the patchwork and badly fitted character which has hitherto distinguished amending Sanitary Acts. It may be possible now to draft such Acts so as to enlighten and not obscure existing law. The Public Health Act, 1875, is indeed a great gain, and the Local Government Board deserves and will receive much credit for it. But hardly has the Board achieved this work before it proceeds, so far as itself is responsible for the administration of the Act, to render it foolish. Among the amendments contained in it is one (Section 286) giving power to the Local Government Board to unite districts for the appointment of medical officers of health. This provision, although directly contravening the avowed policy of the Board, was felt to be requisite in order that the Board might have some chance of escaping from the muddle of administrative futilities into which it had blindly plunged in its administration of the Public Health Act of 1872. But the Board has used its lately acquired additional power simply to make confusion worse confounded. It has endeavoured and is endeavouring to put the power into operation by promoting combinations without any rational reference to the duties to be performed in them. Indeed, it avows that it would never seek to define the duties until the combinations were made; and is no doubt, as are its inspectors, surprised to find that local authorities very generally object to pay for "a fancy article" in medical officers of health.

Our Commission has been engaged on two important inquiries during the past year—the Sanitary Condition of our Public Schools, and the Management of the Public Lunatic Asylums. With regard to the former, it was felt, after the revelations made by our Commissioners last year, with respect to the disgraceful sanitary condition of the two chief universities, Oxford and Cambridge, and the death from fever of several of the undergraduates, that a visit to some of our chief public schools would not be without benefit, and that any definite suggestions our Commissioners might be able to make for the better protection of boys against the introduction of zymotic diseases would be of service to the governing bodies. The fact that during the present year we have had to record three severe and extensive outbreaks occurring at three different scholastic institutions—namely, Mr. Müller's Orphanage, Bristol; the *Cornwall* training-ship, and Uppingham School—shows the necessity for establishing some very distinct regulations for the protection of schools against the introduction of epidemic diseases. The inquiry extended over the following subjects:—1. The connexion of the school with the town. 2. The precautions adopted to prevent the introduction of infectious diseases into the school. 3. The measures taken to isolate cases in the event of an outbreak occurring. 4. The general sanitary arrangements with respect to waterclosets, cisterns, waste-pipes, &c. 5. The relative proportion of working to playing hours, and what supervision protects the weak and delicate from engaging in too much mental or physical exertion. The schools as yet visited have been Eton, Winchester, Harrow, Rugby, Marlborough, Shrewsbury, and the "Royal Medical College" at Epsom. Reports on most of these have already appeared in our columns, and the remainder will be completed during the ensuing year. Our Commissioners have been pleased to find that no case of wilful neglect could be brought against any of the schools visited. The domestic arrangements in every case were excellent, and attempts had been made to keep pace with the sanitary requirements of the day. It was interesting, however, to observe how these varied at the different schools. At Marlborough and Rugby, where the medical attendant is responsible and consulted by the governing body, the arrangements were complete, and left little to be desired. At Shrewsbury also, which has the advantage of having Sir James Paget as a member of the governing body, the sanitary details were in thorough order. At the older schools, Eton, Harrow, and Winchester, which ignore the services of the medical man, except in cases of illness, and which employ no system whatever of medical supervision, matters were not so satisfactory, and much remains to be done to render their arrangements complete. We need hardly say there is little use in entering on extensive schemes of sewage-disposal or water-supply if at the same time no system is adopted by which disease can be discovered and isolated when imported into the school on the boys' return from the holidays. This supervision ought also to be extended to the examination of the boys, even whilst in reputed health, at frequent intervals during term time, for in this way acute diseases may be earlier detected and checked by treatment, the more insidious forms of chronic disease brought to light, and the influence a boy's work in school or in the playground is having on him, can be registered. The medical attendant of a school holds as important an office as the head-master; and, whilst the latter is responsible for the boys' moral training, the former should have the sole responsibility of his physical well-being. The purposes of our inquiry into the management of Lunatic Asylums are to ascertain the general character and efficiency of the provisions made for the insane in asylums and the conditions of their daily life, to discover the measures, and, as far as possible, to formulate the treatment, adopted for the cure of remediable or recent cases, and the means of relief for incurable or chronic cases. We believe this inquiry will help to furnish the profession with the much-needed data for personal opinion on many urgent questions relating to the treatment in public and special institutions of patients labouring under the various forms of mental disease. It should also contribute to the sum of evidence required to determine moot points with respect to the diverse methods of treating insanity, and it may do some service by exposing and thereby removing and redressing grievances affecting the insane. The asylums visited and reported on have been Brookwood and Hanwell: others will follow, and next year we hope to show that the objects above indicated have been fulfilled. Our Sanitary Commission have also issued reports on other subjects of interest. In April, in consequence of a statement of Lord Robert Montagu, "that Folkestone might be matched with any town in England for pestilential holes, from which scarlatina and fever were never absent," our Commissioners visited the town, and were able to report that there was nothing in the present condition of Folkestone to excite alarm, and that the town at the time was perfectly healthy; they made a few suggestions, chiefly with respect to the water-supply, which was without doubt the weak point in the sanitary arrangements of the town. Reports also have appeared in connexion with our Commission on the Dwellings of the Poor, which have acquired an additional interest from the passing of the Artisans' Dwellings Bill. The buildings of the Improved Industrial Dwellings Company were selected for inspection, as representing the class of building which is most likely to return a dividend at the least expense to the occupiers. These buildings were found immeasurably superior to the ordinary dwellings which artisans are usually compelled to inhabit, although we were obliged to criticise one or two minor points in the sanitary arrangements. In concluding this notice of the work done by our Commission, we must advert with some satisfaction to the labours of the past. The authorities at Cambridge have consented at last to appoint a medical officer of health for the town. At Oxford we understand efforts are being made to improve the water-supply and divert the Hincksey sewage from contaminating it. The Brentford pauper children are removed from their dismal quarters; the Knightsbridge Barracks have solved the question of removal and restoration by their own decay; and the huts on Woolwich Common have been removed.

We are pleased to record that, after a lapse of three years, Mr. Simon's Sanitary and Scientific Reports once more make their appearance. Their suppression in the first instance must remain a permanent stigma on Mr. Stansfeld's administration, for all sanitary workers had been accustomed to look forward to them as giving the most accurate and advanced information on points connected with sanitary medicine. The present volume commences with an able article from the pen of Mr. Simon on Filth Diseases and their Prevention; then follow a series of admirable reports for the four years 1870 to 1873, from the medical inspectors, of outbreaks of fever in different districts throughout the kingdom. Among these we must distinguish Dr. Buchanan's report on the Outbreak of Enteric Fever at Caius College, and that by Mr. Netten Radcliffe and Mr. W. H. Power, as being especially able and interesting. The volume concludes with a report by Mr. Netten Radcliffe of an inquiry concerning the Prevention of Excrement Nuisances in Towns and Villages. This report is a valuable contribution to sanitary literature, and is a complete and exhaustive inquiry into probably the most abstruse problem concerning ourselves and our immediate successors. The medical inspectors have gained a high place in the estimation of the public, and the volume shows that it is not their fault at least that sanitary reform still lags behind. If their counsel and opinion were sought and attended to by those in authority, sanitary legislation would no longer be incoherent and ineffectual. The causes of preventable diseases are now so well understood and explained, that the responsibility rests with the public and the Legislature if they omit to carry out the means indicated to eradicate them.

The enormous number of steamships of large tonnage consequent upon the trade to India, China, and Australia, through the Suez Canal, and the great increase of first-class Transatlantic travelling, has at length compelled the Marine Department of the Board of Trade to look somewhat closely into the qualifications of medical men who offer themselves for service afloat. As it was found by a Parliamentary return published in June last that of those who signed articles, many were unregistered, and some unqualified, a circular order has been issued, directing that none but surgeons registered under the Medical Act are to be permitted to do duty afloat. The machinery for carrying out this order is, however, as yet very imperfect as regards vessels other than emigrant ships, but there is no doubt that the tendency of the movement is to raise the status, and by consequence the pay and position, of men attached to the Marine Medical Service. The Board of Trade has during the year issued revised scales of medicines and medical stores for the use of emigrants afloat. These were much needed, as the old scales were antiquated in a superlative degree. But the authorities at Whitehall have, during the past year, done literally nothing in the way of helping the shipowner to procure sound and healthy vital material wherewith to man his ships. So much time is taken up with "Plimsollian" proclivities, that Sir Charles Adderley and the member for Derby are entirely oblivious of the fact that, however seaworthy vessels may be, they will and must be lost if insufficiently or inefficiently manned. Rotten seamen increase in numbers year by year, and the official inquiries held lately on account of outbreaks of scurvy show that a large proportion of men shipped abroad are physically unfit for any sort of work afloat. An unusual number of cases of scurvy have occurred, caused chiefly by carelessness in serving out the lime-juice, and in two cases out of the ten investigations held this year the master was convicted and very heavily fined. Until, however, the provisions of the 10th section of the Merchant Shipping Act, 1867, are made obligatory instead of, as now, permissive, ships and valuable lives will continue to be lost at sea.

Port sanitary work progresses steadily, but no importation of epidemic disease has occurred either in London or at any of the outports. The school-ship *Cornwall*, moored in the Thames, has suffered from a very severe outbreak of enteric fever. About 90 per cent. of the ship's population were affected, and the cause appears to have been partly due to the faulty mode of conveying the drinking-water from the shore to the ship. This outbreak and others (ophthalmia and scarlatina) that have occurred during the past two years show pretty clearly that if school-ships are to be continued and, as is reported, increased in number, some definite system should be adopted, both as to their fittings and special sanitary arrangements. At present, no two school-ships in the United Kingdom are arranged alike; and skilled official supervision at the time that these ships are being fitted for their occupants is very much needed.

The principal matters of note during 1875 in regard to Epidemiology were the appearance of cholera in Syria, and the further development of plague in Mesopotamia. Cholera broke out at Hamah in Northern Syria some time during the first quarter of the year, and subsequently extended over a large district, spreading into Karamania in the north and Palestine in the south, attacking all the principal ports, from Alexandretta to St. Jean d'Acre, on the seaboard, and visiting Damascus and the Haman in the east. The disease, moreover, passed the Euphrates into the pashalek of Diarbekr. In Damascus, Aleppo, Antioch, &c., the malady was very fatal. The origin of this outbreak, still not extinct, is obscure. Cholera had been in existence two months at Hamah before the nature of the disease was discovered, and no inquiry deserving of the name has as yet been made into the antecedents. Plague, which had shown itself on the Lower Euphrates among the Afij Arabs the preceding year, appeared again early this year among the Arab tribes living lower down on both banks of the river. In this outbreak the disease manifested considerable intensity, and was very fatal. It affected the district lying between Diwanieh and Samara, and extended from the Tigris on the east to the Sea of Nedjef on the west. Of the several developments of plague since its reappearance in Mesopotamia in 1867, this was by far the most extensive and fatal. Comparing the several appearances of the disease, in the Hindieh marshes (Babylonia) in 1867, in Persian Kurdestan in 1870-71, on the Lower Euphrates, in the district of Benghazi (regency of Tripoli), and Eastern Arabia, in 1873-74, this later appearance on the Lower Euphrates suggests that the disease is gaining strength in each successive development. Into Fiji, just after its annexation to England, measles was imported, and caused enormous mortality. At home the chief points in epidemiology have been the prevalence of scarlet fever, whooping-cough, and measles, which still figure largely in the Weekly Returns of the Registrar-General.

As regards the Public Medical Services there has not been much to record. The Indian Medical Service still holds, and most deservedly so, the first place in the estimation of the profession, and in popularity with the younger members of it. It may not be all that it once was, but it still remains a fine service. Everything is relative in a matter of this kind, and we have only to compare the Indian with the British Medical Service to discover how great the difference in favour of the former service is: the pay and position are better; the country affords scope for the exercise of varied talents and attainments, and there is every chance of merit coming to the front. We wish we could say something in favour of the medical service of the British army at the present time, or prophesy smooth things in regard to it. The year 1875 will be chiefly remarkable for the flood of pamphlets, letters, &c., on the organisation and state of the Army Medical Service. The abolition of the regimental system was unpopular. We never expected it to be otherwise; but we hold that if the medical service is to become professionally efficient, progressive, and respected, it must be emancipated from that narrow system on which it has been moulded in the past. The whole organisation of the army is changed or changing, and the sooner the authorities have made up their minds definitely as to the future organisation of the medical service the better, for a feeling of insecurity seems to have run through it from top to bottom. Only the other day a professor of medicine, in opening the session of the Royal College of Surgeons, Ireland, publicly warned medical men against the army, in one of the most outspoken and well-considered addresses which we have yet read on this subject. The year closes with the usual advertisement announcing the next competitive examination for entrance into this service. As soon as the just and well-founded grievances are redressed we shall be prepared to advocate its claims, and not before. Meanwhile, let those who are thinking of entering it pause and peruse Dr. LITTLE's remarks in the address to which we have referred. Turning to the Navy, we have no hesitation in declaring that at the present time a medical officer would be better off in that service than in the army. Mr. WARD HUNT has had his share of abuse in other directions, but in this he deserves great credit. Once a service has got a bad name it is long, very long, before confidence is restored, and the Admiralty is still suffering for its past sins. We are utterly opposed to a practice of abusing Government services simply because they are Government services. We take it to be the duty of the journalist to bring judgment, fairness, and a sense of responsibility to the work of advising young men in the choice of their career, and to recognise any desire on the part of the Government to deal fairly with their servants. The navy then is, to those who have no aversion to a life at sea, a good service for medical men, and a far better one than it ever was before. Now that a knowledge of natural science and biology is more generally diffused, it affords scope, too, for the prosecution of scientific researches in these directions.

The General Council of Medical Education and Registration met in June under the Presidency of Dr. ACLAND, the successor of Dr. PAGET, and a passing tribute of gratitude as well as of respect is due to the late President for the courteous and genial as well as able manner in which he discharged the duties of his high and responsible office. Dr. ACLAND gave an opening address, in which he briefly reviewed the events of the past year, so far as they related to the proceedings and action of the Medical Council. He referred to the Bills of Sir JOHN LUBBOCK on the Conjoint Scheme, and to Mr. COWPER TEMPLE's Bill for the Registration of Women to whom licences to practise had been granted, to the Reports of the Visitors of Examinations, and to the large subjects of scientific education and the improvement of the public health. Various questions of interest were discussed by the Council. The importation of Dr. ROLLESTON into the Council gave additional interest to some of its debates. The Conjoint Scheme met with little attention, and those who still continued to believe in it were in a minority, and looked upon as men of great faith. The two subjects which occupied most of the time of the Council were the Reports of the Visitors of Examinations, and the question of the Medical Registration of Women. The Reports of the Visitors of Examinations were then read, which included those of the Universities of Oxford, Cambridge, Durham, Edinburgh, Aberdeen, St. Andrews, and Dublin; those of the Colleges of Physicians and of Surgeons in London, the Colleges of Physicians and of Surgeons and the Society of Apothecaries in Dublin. The Reports on the Medical Examinations of the Universities of Oxford, Cambridge, Aberdeen, and Edinburgh were favourable, the only point noted by the Visitors of the University of Oxford being the absence of dissection, in regard to which some difference of opinion was expressed by members of the Council, some thinking it of importance, others regarding it as an unessential part of the examination. We can entertain but one feeling in regard to it, having always insisted upon the necessity of such dissection as the best means of enabling a correct judgment to be formed by the examiners of the knowledge of the candidate in this subject, which, as Professor Huxley has said, is the one thing that is well and thoroughly taught in our profession. The remarks of the Visitors in their Report on the University of Aberdeen raised the question of examinations being conducted by the teachers of the same or of other schools; and the different views were acutely expressed by Professors Turner and Rolleston, the former maintaining that a man who selected his wife from a family with the members of which he was well acquainted was more likely to be well suited than he who took one at a garden party, whilst Dr. Rolleston compared teachers examining their own pupils to men auditing their own accounts. Perhaps a compromise is the best means of settling this point, the board of examiners in every case being partly composed of the teachers and partly of extraneous elements. The Report on the University of St. Andrews led to some severe criticism, Sir D. Corrigan going so far as to ridicule the idea of registering the medical degrees given by this University, since there was no infirmary, no dissecting-room, no chemical laboratory, and no medical students, rendering it impossible that an *annus medicus* could be kept. There can be no doubt that if this University is to continue granting degrees some material alteration must be introduced into its method of examination. The examination at the Royal College of Physicians of London also came in for some caustic remarks from Sir William Gull. The action of the General Council in the case of this College and in those of the College of Surgeons, the University of St. Andrews, and the Apothecaries' Hall of Ireland, in all of which serious defects were noted by the Visitors, was marked by singular inconsistency; for whilst, in the former, as well as in several other cases, the Council passed a resolution calling attention to the faults of the examination, it declined to do so in the case of the latter. Upon the whole, we cannot doubt that these visitations are of immense importance, and we sincerely trust that they will be continued from time to time by the Council, the Visitors being in all instances directed to report without previous communication with the examining body. This at least is certain, that great improvement has resulted in many instances in the character of the examination when the attention of the more sensible members of a licensing body has been directed to glaring defects.—The question of the registration of women was raised in the Medical Council by nothing less than a letter from the Lord President of the Privy Council, asking the General Council's opinion not only on Mr. Cowper-Temple's Bill for the Registration of Women with Foreign Medical Degrees, but on the general question, "whether women ought to be able to look to medical practice, or certain branches of it, as open to them equally with men, as a profession and means of livelihood." Mr. Simon, speaking for the Lord President, added: "I am to say, that as Government may have to express an opinion on this general question, with regard, on the one hand, to women who desire to obtain legal status as medical practitioners in this country, and on the other, to the examination rules or conditions which prevent them from accomplishing their wish," his Grace would be glad of any observations with which the Medical Council might see fit to favour him. There has not been such sensation produced in the Council as this letter caused since a former letter by the same amanuensis, on the absurd system of half qualifications, which, however, still survives. Our readers are familiar with the answer made by the Council as regards the admission of women to the Medical Register. Dr. Andrew Wood, in that direct and outspoken style for which we all like him, wanted to return a decided negative to the question of the admission of women, but the majority of the Council thought it best to content themselves with replying that "the Medical Council are of opinion that the study and practice of medicine and surgery, instead of affording a field of exertion well fitted for women, do, on the contrary, present special difficulties; but the Council is not prepared to say that women ought to be excluded from the profession." Having declined to say that women should be excluded, it went on to say that if it should appear to the Government and the Legislature that women should obtain a legal status, then, in the interests of public order, their education and examination should be conducted entirely apart from those of male students. In short, the Council leaves the responsibility of admitting women to the profession where it should be left, with the Legislature, only protesting against an education in which the male and female students would study together. The other questions discussed by the Council need not detain us here.

The meeting of the British Medical Association took place in Edinburgh in August, and of course was a successful one. The Edinburgh school acquitted itself in a way worthy of its fame. Dr. Begbie's Address in Medicine was very learned and able, consisting mainly of a comparison of modern and ancient medicine, and erring, if in anything, in too modest an estimate of the modern art of which he is so worthy a representative. Sir Robert Christison defended, with his usual boldness and vigour, the existing system of education by lectures and of examination by nineteen bodies. He strove hard to reverse the general opinion that this system is not satisfactory. Professor Lister gave demonstrations of his Antiseptic System, which impressed hitherto doubting minds, and Professor Spence showed that it was possible to get very good results without the antiseptic system. Pending the settlement of the question of the admission of women to the profession, the "powers that be" of the British Medical Association had quietly settled the question of their admission to the Association in their favour, and papers by one or two ladies were announced. This gave rise to a warm discussion, ending in a resolution that the opinion of members be taken on this question before next meeting.

It is always the most painful part of our duty to record the death of members of our own profession. There has been nothing so sadly premature, perhaps, this year as that of Dr. Anstie in 1874, but a few names of those who have left us will indicate that our loss has been great:—Kiernan; Surgeon-General O'Flaherty; Robert Adams, of Dublin; Deputy Inspector-General B. T. C. Scott; James Dawson, Wray Castle, Windermere, M.R.C.S. 1806; Thomas Paget, of Leicester; Dr. George Robinson; D. P. Evans, M.B., of Belper; Professor Oswald Home Bell, of St. Andrews; M. Demarquay; J. F. Clarke; Dr. Peter Mere Latham; Sir Charles Locock; John Hughes Bennett; Wm. Hey, of Leeds; M. Duchenne; M. Lorain; John Hamilton, of Dublin; Geo. Allarton; Dr. Maunsell; Henry Ashton; to say nothing of numerous other practitioners who have died in the midst of active duties of general practice. When we think of the acute intellects that were once represented by some of the above names, and then consider that all their contributions to medicine and science are over, we may at first feel sad; but our sadness is qualified by considering the immortality of much of the work they have done, and by the perpetuity of the influence which they have impressed on their successors. We cannot in this connexion forbear one word of respect to the memory of John Churchill, not himself a member of the profession, but once the publisher of The Lancet, and pre-eminently the publisher of the profession.

There are various events of a somewhat miscellaneous character which should scarcely be overlooked, even, as we have said, in the medical history of the year. Captain Boyton in May crossed the Channel in his swimming dress from Dover to Boulogne, paddling his way. The suffering endured was considerable. He became sleepy, and actually slept, starting up afterwards to find himself paddling. Green tea refreshed him and removed the unpleasant sensations. He was in the water twenty-three and a half hours, and though fatigued at the end of this time, was yet not so much so as might have been expected. In August Captain Webb performed the still more marvellous feat of swimming across the Channel. Mr. Henry Smith favoured us in September with a satisfactory account of Captain Webb's physical condition and appearance. The feat remains unprecedented, and is likely to continue unique. On the 29th of May a new Arctic Expedition started very auspiciously with unprecedented provisions for the protection of life and the facilitation of discovery, of which we were able to give a somewhat detailed account, through the courtesy of Fleet Surgeon Colan, senior medical officer of the expedition. In him and his colleagues, the profession and natural science are well represented. As we write the Prince of Wales is in the middle of a Royal visit to India, where he is receiving the welcome to which his rank and the urbanity of his manners entitle him. Every care is being taken to protect His Royal Highness from injurious climatic influences. He is accompanied by Dr. Fayrer, physician to the Council of India, who accompanied the Duke of Edinburgh on his Indian tour.

We must now take leave of our readers for the year 1875. We have said little about ourselves. We shall leave our pages to speak for themselves. Every kind of article has been found in them. Every branch of medicine has had its share of attention. Nothing affecting the honour and dignity of the profession has been unnoticed. Questions in Pathology and Practice have naturally had precedence. And some very important ones have been started in our columns. Witness the views of croup set forth in the lectures of Sir William Jenner, and all the discussions to which they gave rise; the discussion as to the advantages of ether over chloroform; the discussion between Sir Henry Thompson, and his critics as to the ulterior results of lithotrity. If there is one part of this journal of which we are more disposed to boast than another, it is the reports of the proceedings of the Medical Societies, which of late we have been able to furnish with promptitude and faithfulness. But we shall desist from boasting, remembering that for much of the material which makes up The Lancet we are indebted to the busy practitioners of the country and of the metropolis, who make it the medium of their opinions and their experience. We have only to thank our various contributors, and to assure all practitioners who have anything at once true and new in medicine to announce, that these pages are at their disposal. The day on which we say our last word for the year to our readers is a great day:—

"Heaven's youngest-teemed star
Hath fix'd her polish'd car,
Her sleeping Lord with handmaid lamp attending;
And all about the courtly stable
Bright-harness'd angels sit in order serviceable."

We wish our readers a happy Christmas. Even where there are elements of sorrow there may be excess of joy. Our national way of keeping Christmas is not without some suggestion of coarseness. But there is more in it, after all, than mere roast beef and plum pudding. We bury old grudges at this time, and forget old offences. We catch fresh inspirations of generosity and charity, which make the years more magnanimous, and add to the still too scanty stock of goodwill among men.

Another death from the incautious use of powerful drugs as alleviators of pain has occurred. Lady Chesterfield died on Monday last at Edinburgh from an overdose of tincture of opium. The lamentable frequency of disasters of a like nature forces on the profession the duty of protesting earnestly against a fashion which permits ladies to keep bottles of chloroform and laudanum in their bedrooms. The public should understand that even in the hands of careful surgeons the administration of these drugs, especially the former, is not unaccompanied with danger, and that their use by non-professional persons is unjustifiable and necessarily reckless. The sad fate of Mrs. Childers is fresh in the memory of all, and the present catastrophe enforces the lesson taught by that event. The indiscriminate practice of self-doctoring generally cannot be too strongly discountenanced.

Annotations.

"Ne quid nimis."

THE FREE SYSTEM AT THE QUEEN'S HOSPITAL, BIRMINGHAM.

The resolution of the governors of the Queen's Hospital abolishing privileges and adopting the free system was at once followed by the appointment of a sub-committee, on which were the chairman and two other members of the Medical Board, to carry the scheme into effect. The report of that sub-committee, which has already been approved by the Hospital Board, is now before us, and we purpose showing how it is proposed to apply the free system with proper checks as to inquiry into social fitness and with proper selection of suitable cases. The report starts with the proposition that a hospital is designed to deal with two classes of patients—"1. Those who, from accidents or the attacks of acute disease in a serious form, must be passed immediately into the wards as in-patients. 2. Those who, having been in-patients, still require for a time the supervision of the staff in order to effect a permanent cure, or who, though not sufficiently indisposed to require in-door treatment, are obliged to seek at the hospital the advantage of skilled consultants or of specialists, whose advice, while necessary, is beyond the pecuniary means of the applicants." The first class is to be admitted without any inquiry into social and pecuniary fitness, and without registration fee. The second class, which is now altogether too large, it is proposed to diminish by the weeding out of trivial cases which should be attended to by private practitioners or in sick clubs, and by a careful system of inquiry into the social status of the applicants, combined with a registration fee of one shilling for each case.

The general superintendence of admissions is to be entrusted to the House Committee, and all applicants declined by the inquiring officer will have liberty of appeal to the House Committee for a revision of their applications. That officer is directed to make inquiry as to the available income of the applicant, number of children, &c., and "in ordinary cases, not decided by special circumstances, an income of 35*s.* a week, with not more than four children or six persons in the family, is to be regarded as the limit of pecuniary fitness." No paupers, except when bringing special forms of recommendation from a recognised parochial medical officer, are to be received. All cases of peculiar urgency or importance which have been under the care of a medical man may, upon his certificate, be admitted.

These are two concessions to the medical profession of the district which are of the highest importance, and ought to insure for the hospital their cordial support and co-operation. All cases needing special advice or treatment, prolonged watching and nursing, and such attention as cannot be provided in any private house, may thus, at the bidding and on the recommendation of any qualified practitioner, be franked admission to the hospital, a boon which only those medical men who have had protracted surgical accidents or medical diseases under their care in the houses of the poor can fully appreciate.

The scheme is put forward in a tentative and modest spirit, although it evidently has cost much thought and careful consideration. The adoption of the free system by a large general hospital is a new feature, and the committee, having no precedents to guide them, have wisely submitted their recommendations as an experiment in hospital reform, and they trust to, what we think they will undoubtedly obtain, "the co-operation of the governors, the general committee, the staff of the hospital, and the patients themselves, for the gradual perfecting of the arrangements." Other minor reforms—as the reduction of the qualifications of governors from two guineas to one; the increase in the number of visitors with authority to inspect the hospital at any time during their year of office—show that the Committee are alive to the necessity of making the hospital as popular as possible, by increasing the number of their constituents, and by allowing representatives from among them to see that the work of the hospital is done thoroughly in all its departments at all seasons. We trust that a continued and increasing prosperity may follow these sincere efforts to promote the usefulness of the institution.

THE TRANSMISSION OF POTABLE WATERS.

The last report of the Rivers' Pollution Commissioners relating to domestic water-supply gives some particulars on this subject, which are the more important because the storage of water and its distribution to communities often necessitate its transmission through mains to a considerable distance.

There is no doubt that water originally clear is sometimes rendered turbid during its transmission through cast-iron mains, the turbidity being due to the rusting of the iron. Hard waters have but little action upon cast-iron, but soft waters generally attack the pipes so vigorously as to weaken them by deep corrosion, and to block them up by the formation of concretions. This corrosion and its consequences can, however, be prevented by a process invented by Dr. Angus Smith, which consists in heating newly-cast mains or pipes to about 500° F., and then dipping them perpendicularly into a bath containing a mixture of pitch and heavy coal oil, maintained at a temperature of about 430° F. The pipe is raised after a few minutes, the surplus composition runs off, and a black shining varnish remains on both the inside and outside surfaces of the pipe, even penetrating deeply into the pores of the iron. It is essential, however, that the pipes should be newly cast and hot.

Much injury to water frequently occurs by the improper construction of the joints of the mains. It is a frequent practice to caulk the joints with tow next the interior of the pipe, and then to run the joint with molten lead. The Commissioners condemn this practice strongly, because it allows, in a long main, the contact with the water of a large amount of hempen or other matter, which renders the fluid disagreeable both to the taste and sight, and affords, moreover, a nidus for the breeding, development, and decay of animalculæ. It is reported that the polluting effect of tarred yarn joints also is equally marked, and is not eliminated even after twenty years. There are two remedies for these evils. Turned and bored joints may be employed, or the joints may be carefully pointed inside the pipe with Portland cement, the latter plan, however, being only applicable when the main is large enough for a man to enter. The East London Water Company recently laid a main 4 ft. in diameter and 18¾ miles in length upon this latter plan. Every pipe was lime-whited inside from end to end, and the crevices that usually exist between the end of one and the socket of another pipe, when laid, were filled with Portland cement, so as to produce as even a surface as possible to the running water. All hemp dust is thus shut off from the water, and the joints in many parts are indistinguishable. The analysis of the water conveyed by these pipes showed an entire absence of deterioration.

In discussing the demerits of leaden pipes for the conveyance of water from the main to the houses, the Commissioners report that "the commonly received opinion that soft waters necessarily act upon lead is erroneous," for, whilst many samples attack the metal when its surface has been recently scraped, comparatively few have any action upon the tarnished metal. Waters that act violently upon lead lose this power by contact for a very short time with animal charcoal, this immunity being obtained by the solution of a minute trace of phosphate of lime from the charcoal. The Loch Katrine water, and that supplied to Manchester and Salford, both act powerfully on lead, but no case of lead-poisoning from the use of these waters has as yet been recorded. But, although the action of water deficient in carbonic and phosphoric acids upon lead is transitory, some polluted shallow well waters are found to act violently and continuously upon leaden pipes, and several instances of poisoning from this cause have occurred.

THE CRITICAL FACULTY IN MEDICAL OFFICERS OF HEALTH.

The remarks which we had recently occasion to offer* concerning the unwisdom of the tendency to set themselves up as professional critics which had been exhibited by some medical officers of health, find additional justification in the paper read by Dr. Gilbert Child, health officer for Oxfordshire, at the Social Science Association last week. It appears that a consideration of "the necessary limits to the applicability of the method of statistics, with especial reference to sanitary investigations," has led Dr. Child to the conclusion that statistics based on the returns of causes of death are so fallacious that the "large amount of public money" expended upon their "compilation and manipulation" may be said to be "squandered"; and further, that not only is it impossible at the present time to obtain accurate statements of the number of fatal diseases, but "there is no reason to suppose" we ever shall or can obtain such. The affirmation is that the causes of death are first incorrectly returned by the medical practitioners, and afterwards incorrectly classified by the statists. Of course cases of actual and possible mistaken diagnosis, of ignorance, and of suppression of the truth in respect of fatal diseases were adduced, and in commenting upon these and upon his general experience as medical officer of health for Oxfordshire—one of the seven smallest counties of England as regards population—Dr. Child was led, in the discussion which followed the reading of his paper, to say (hastily and unguardedly let us hope) that the causes of death as returned by the general medical practitioners were not worth a farthing, while those returned by coroners were not worth a twopenny piece!

Now, upon the statistical side of the question, we have simply to observe that Dr. Child has nothing new to tell us; experienced statists have years and years ago instructed us in the proper use and limits of the statistical method as applied to the mortality returns, and practical people are content to believe that, imperfect as those returns may be, they do yield results of some value now, and that the progress of medical education is year by year reducing the imperfections of the record. But the important point raised by Dr. Child's paper is, after all, this: Is it expedient (to say the least) that a professional brother, "armed with a little brief authority," should make use of the opportunities which his public position has afforded him of becoming acquainted with any shortcomings on the part of the general practitioners of his county, to blazon forth such shortcomings before an audience so little competent to discuss questions of medical education and diagnosis as ordinarily would be found assembled at the Social Science Rooms? Is not such a course likely rather, in the first place, to irritate the great body of general practitioners, and goad them into an antagonistic position upon all matters of public health administration; secondly, to foster that "depreciation of medicine at head quarters" of which we have before spoken; and, lastly, to strengthen immeasurably the hands of all opponents of sanitary work?

THE PROVIDENT DISPENSARIES AND FRIENDLY SOCIETIES IN MANCHESTER.

The great scheme for organising a number of provident dispensaries in Manchester and Salford, to be worked in unison with the free medical charities, is still only in course of evolution. The latest phase of the process has called forth a smart discussion in the *Manchester Guardian.* It took the shape of a proposal to admit the friendly societies into the provident dispensary system. It will be readily understood that this proposal was open to two objections—that it was interfering with provident arrangements already made, and creditably made, and, secondly, that it was interfering with the interests, in some sense vested or established, of the doctors of clubs and friendly societies. These objections have been ably answered by Mr. O. Hanlon. But they are not without much force. It will be a lamentable mistake if the promoters of this most praiseworthy experiment in Manchester, in trying to extend forethought and independence in medical matters among the working classes, introduce disturbance into the only provident arrangements that exist, and excite the prejudice of those medical men who for years have been working laboriously in connexion with friendly societies. It was not certainly the members of benefit societies whose improvidence required the early attention of the Council of the provident dispensaries. And we trust that either these societies will be undisturbed, or the interests of their medical advisers will be insured. It is quite true that they do not pay their medical officers as they should. But it is also true that some of them have acted very creditably in this matter, and that they are self-supporting and independent institutions, whereas the provident dispensaries have still a large charitable element in them. We make these remarks from a pure desire to see the Council avoid the cheap glory of working in other men's fields of labour, believing that there is a huge mass of material outside the friendly societies on which to try the most interesting public experiment that has been made to put the medical attendance on the artisan class on a satisfactory footing.

FEES FOR MEDICAL ATTENDANCE.

An attempt has recently been made by the medical profession in Madras to assimilate the scale of fees in that Presidency to that of the Presidencies of Bengal and Bombay; and this has led to a correspondence between the officiating Chief Secretary to the Government and Dr. Balfour, the Surgeon-General, Indian Medical Department. The subject has, moreover, been a good deal discussed and commented upon by the Indian papers. According to an order of the Government of India, the amount of remuneration for attendance on the families of public servants is left to private adjustment. By a well-known and long-established custom in the Bengal and Bombay Presidencies, the repayment of an equivalent of one week's income was understood to be the fee for medical attendance for the year; and, not to enter into a number of details, the fees for consultation, professional visits, confinements, operations, and so forth, have also been tolerably well known. The doctors in Madras, probably having deemed it expedient that something like uniformity should be adopted, projected a scale of remuneration for their professional services in these respects, to which, however, very strong exception has been taken. Dr. Balfour urges that the scale is, in his opinion, a very fair one, and contrasts favourably with the rates obtaining in the sister presidencies; and he is very careful to point out that the fees have been fixed, not to affect the indigent, but to protect practitioners at the presidency from gratuitous or inadequately remunerative attendance on the rich, and on those who have no official claim for their services, and that now, as ever, they are performing a large amount of work either almost or quite gratuitously among the needy. Those classes who have no means or small means may, therefore, be altogether put aside, as the scale of fees was only intended to apply to the rich and well-to-do, for whom the scale is neither a new nor an excessive one. There is not, Dr. Balfour says, in the large city of Madras a single non-official medical practitioner who has come from Europe—a fact which, at any rate, proves that there is nothing to tempt them to come out. But to this the Government replies that the scale of fees agreed upon by the doctors is excessive, and Dr. Balfour is desired to communicate this opinion to the medical men in Government employment. We very much regret that this question has sprung up, although it is natural that it should do so. It is well known that medical fees in Madras have been diminishing in amount, and that if the Government hear of every case in which an apparently excessive fee has been demanded, they never hear of the larger number of cases in which a very inadequate one has been tendered. A medical man, and especially a medical officer, feels that he is a public servant, that anyone has a claim on his services, and that those who cannot afford to pay have still a claim which he is quite ready to recognise; but what he does not recognise is that those who are indubitably in a position to pay should put a value on his reputation, skill, and services lower than seems to him reasonable. Still, as we have said, we regret the occurrence of this discussion. The case is undoubtedly one of much difficulty and delicacy, and anything like a combined movement on the part of professional men, serving under the Government, is certain to lead to misconstruction, and very probably to imputations that can neither be accepted nor repelled without some sacrifice of professional dignity. We hope never to see professional men animated with the spirit of a trading community, and we believe that we never shall see it, especially in India, so long as the medical officers continue to regard their skill and information as a trust to be used for the common good of everyone; but if the exercise of their profession is to be a source of remuneration at all, the question of what is an adequate and reasonable remuneration must, of course, arise. Official incomes in India being well known, there should be no difficulty about it, and we can understand that a medical man would prefer to give his professional services than to have them valued at a price so far beneath their worth as to make him feel that he had not been regarded with the respect to which he was fairly entitled.

FORCE AND WORK.

WORK without implies work within. No exercise of force can be made except by the generation and use of force of which no part enters into the external result. The use of muscles involves use of nerves. The external force, if exerted by a muscle, is only part of that which it produces. Now the proportion between these two in their several degrees is a subject of great practical importance, and some interesting facts have recently been published by Helmholtz. From these it is clear that the greater the external force exerted the greater is the proportion of the needful internal force—that is, great exertion is more wasteful than moderate exertion. Then force has to be evolved in proportion to the external work done, and therefore the greater is the wear and tear of the animal machine. The same increased proportion of non-productive work is seen when the external energy is below a moderate amount. It is found, for instance, that in walking, a speed of three miles an hour gives the most economical use of the forces. No doubt in these facts we have an index to much of the ill effects of the present high-pressure rate of work and life. The waste of force is out of proportion to the work done. More is effected in a given time, but the body feels it more, and its working period is proportionately shorter. These facts cannot be too often repeated or too constantly remembered by those who have the regulation of labour.

THE PRINCE'S TOUR.

WE have received intelligence as to the health and movements of His Royal Highness up to the 26th ultimo. The *Serapis* left Bombay on the preceding day destined for Ceylon, visiting Goa and Beypore *en route*. The future movements of the Prince would be decided by the reports received at Ceylon as to the movements of cholera which had been prevalent in Mysore, and the Madras Presidency. The alteration in the programme, as regards the shooting trip to the Annamully Hills, and a visit to Seringapatam, has already been made known, as well as the Prince's subsequent visit to Madras itself. Our correspondent reports that the Prince "is in excellent health and spirits, and as much pleased with India as India is with him." It was unusually hot steaming in Bombay; indeed the year has been altogether an exceptional one as regards India; and although the Prince has shown great powers of endurance, and an absence of physical fatigue, and has, moreover, stood the heat admirably, it has of course been absolutely requisite to guard against any risk, notwithstanding the disappointment to the inhabitants of those districts and places that have been unvisited. So long as the Prince is in India a similar exercise of caution will obviously be required, but there cannot be a doubt that the climate has thoroughly agreed with His Royal Highness so far, and there is every reason to believe that his visit to India will be a great success, and productive of much good. Our correspondent adds that the Prince's suite are also quite well, after having stood the test of sixteen days' experience of Bombay, Poona, and Baroda.

PROPOSED EXTENSION OF THE BOROUGH OF BRIGHTON.

THAT Hove, so essentially a part of Brighton, should be under a local government and sanitary organisation perfectly distinct from that of the municipal borough of Brighton appears to an impartial looker-on very much like an administrative blunder. We were glad therefore to hear some time since that it was proposed by the Corporation of Brighton to promote a Bill in the next session for the further extension of the boundaries of the borough so as to include the Improvement District of Hove, and the remainder of the parish of Preston, which will probably ere long be absorbed by the rapid extension of building operations. It now appears that the Commissioners for the "town and district of Hove" object to being absorbed by their thriving corporate neighbours, and at a special meeting on the 1st inst. unanimously resolved to oppose the Bill proposed by the Brighton Corporation, and to promote one themselves for the extension of their own district by the addition of that part of Preston parish desired by the Brighton borough. The advantages of consolidation, both from an economical and sanitary aspect, in the case of Brighton and Hove, appear so obvious that it may be hoped the opposition on the part of Hove to the extension of the municipal borough of Brighton to the boundaries of the

Parliamentary borough may yet be withdrawn. That the Commissioners object to be superseded is comprehensible, but it is difficult to imagine that with the Hove ratepayers any serious objection to be incorporated with the borough of Brighton can be entertained.

HEALTH OF THE ARMY AT HOME STATIONS IN 1873.

The Army Medical Report for 1873, a copy of which has just reached us, gives the following summary of the sickness and mortality among the troops serving in the United Kingdom during the year in question. The average strength of the troops, calculated from the weekly sick returns, was 88,957; the admissions into hospital were 67,541; the deaths were 699; the average number constantly sick was 3334. The ratios per 1000 of the strength represented by these numbers are—for admissions 759·2, for deaths 7·85, and for constantly sick 37·47. In addition, however, to those included in the weekly returns, 92 deaths occurred during the year among men detached from their regiments; the average number so detached is given in the Adjutant-General's returns as 6812. The average strength of the force serving in the United Kingdom was therefore 95,767, and the total number of deaths in it 791, being in the ratio of 8·26 per 1000 men. The ratio of admissions is 25·1 lower than that of the previous year; the ratio of deaths is fractionally higher (·31 higher); the ratio of the average number constantly sick is 1·87 per 1000 men lower. All the ratios are lower than those of the average period of the four preceding years.

HUMAN ANATOMY AT CAMBRIDGE.

A discussion is going on at Cambridge as to whether human anatomy should be regarded as a branch of natural science, and admitted to a more prominent and definite position in the Natural Sciences Tripos. Professor Humphry argues that if it is studied simply as a collection of facts and with reference only to the requirements of the medical examinations, it would not constitute a good educational subject, and it would scarcely be worth while to continue the cost and trouble of maintaining a school of Human Anatomy in the University. But if studied as it ought to be in the University, and as it would be if made one of the subjects of the examination for the Tripos, and associated with the thoughts and views which properly belong to it, it then would be an excellent medium of education, combining, in as great a degree as any other subject, the exercise of thought with the observation of facts. With this view it is proposed to connect it with mechanism, comparison with lower animals, development, &c. It is not proposed to make it a compulsory subject, but only an alternative one, so as to offer an additional inducement to medical students to present themselves for the honour examination for the Tripos, and so keep up the connexion between the schools of medicine and natural science.

THE SKULL AS THE TYPE OF RACE.

Prof. Virchow, whose work on the development of the base of the skull will be known to many of our readers, gave at the meetings of the Berlin Academy of Science, according to the monthly reports (Jan. 7th and March 15th), some interesting lectures on evolutional defects of the bones of the skull as a sign of some lower types of the human race. His observations referred to the processus frontalis, squamæ temporalis, and the catarrhine formation of the nasal bones, as positive symptoms of an animal-like, and especially of a monkeyish, type. The existence of the os incæ, which is found in several South American aboriginal races, Virchow holds to be a simple arrest of development of the human type, and of a purely negative character, though it constitutes a very valuable sign for the determination of the ethnological characters, more so than is generally known. The os incæ as a part of the os occipitis, which has not become waited by osseous tissue with the latter, forms the posterior covering of the cerebrum, while the cerebellum is covered by the lower part of the squama ossis occipitis. The latter serves as the place of insertion for muscles; the os incæ, or os interparietale, is, as a rule, free of such insertions. In the aboriginals of Peru the os incæ has been found to be always very large; in the Pampas Indians, however, it is often exceedingly diminutive. In the hare the muscle insertions ascend so high that the os interparietale appears as an oblong square between them. It is to be expected that Virchow will be able to extend his researches over the remains of all the South American aboriginal tribes, since the Emperor of Brazil sent him last summer, through his ambassador at Berlin, several boxes with bones from Indian graves, with a very complimentary letter, in which that enlightened Prince confesses his special interest in the matter.

THE BROWN LECTURES.

Dr. Burdon-Sanderson, F.R.S., has just completed the delivery of the annual course of lectures established by the trustees of the Brown bequest. Taking for his subject the Pathology of Inflammation, the learned professor commenced his course on the 15th inst. by referring at length to the experiments and doctrines of John Hunter. He then combated the attraction theory of Alison and the cellular theory of Virchow, which latter he stated was based on erroneous deductions from Hunter's experiments. In his second lecture he dwelt on the experiments and observations of Dr. J. C. B. Williams, Mr. Wharton Jones, and Professor Lister, and expressed his belief that the paper of the last-named observer had not received the full attention it merited. The third lecture, delivered on the 20th, was devoted to the subject of Exudation, Dr. Sanderson describing in detail the experiments of Cohnheim, which he had himself verified. The fourth lecture was devoted to Inflammation of Non-vascular Tissues, with special reference to recent researches of his own confuting the statements of Stricker and others as to the part played by the tissues themselves in the process.

THE KEIGHLEY GUARDIANS.

The anti-vaccination guardians of the Keighley Board have sought relief in a memorial to the Prime Minister, asking him whether the Government consider it to be the duty of the guardians, holding an opinion unfavourable to the Vaccination Acts, to insist on enforcing a law which they think a law of compulsory infanticide. Mr. Disraeli has no comfort for these guardians. He says, in reply, through Mr. James F. Daly: "It is clearly shown by the above-mentioned Acts that no power is left with guardians or their officers to decide as to the expediency of carrying out either the provisions of the Acts or the regulations of the Local Government Board made in conformity therewith, and that as long as they continue to hold to their offices they are decidedly bound to discharge the duties thus imposed upon them."

DISTURBANCES AT THE FACULTY OF VIENNA.

On the 10th of December very disgraceful scenes occurred at the General Hospital of Vienna, and in the lecture-room of Professor Billroth. The latter has lately published a book on "The Learning and Teaching of Medicine," wherein he attacks the present system vigorously. But, besides this, he lays bare the shortcomings of the students, reproaches them with various failings, and, in fact, blames them in no measured terms. Unfortunately, the supporters of Billroth had organised a kind of ovation to the professor; and the aggrieved students, enraged at this, raised their voices, hissed the lecturer, and both parties at last came to blows. The affair has caused the greatest sensation at Vienna, and the authorities are busy restoring order. Even in the House of Representatives the matter has been taken up, and some members have found great fault with the manner in which Professor Billroth, in his book, has treated the Austrian students.

THE MUCOUS MEMBRANE OF THE UTERUS.

IN Stricker's *Medizinische Jahrbücher* for 1873 there appeared a paper on the Mucous Membrane of the Uterus by Drs. Kunchat and Engelmann. Dr. Engelmann, differing from some of the opinions expressed in that paper, especially those regarding the relation in time between ovulation and menstruation, has republished the paper with some additions and alterations in the "American Journal of Obstetrics." In its present form the paper treats of the mucous membrane of the uterus before puberty; its fully developed but quiescent state; its state during menstruation; of the decidua vera and reflexa during the first, second, third and fourth, and fourth to the ninth months of pregnancy; the development and structure of the placenta; retrograde metamorphosis of the membranes; the expulsion of the decidua and the regeneration of the mucous membrane after parturition.

IN a report of the Sanitary Administration of South Shields recently issued by Mr. John Spear, medical officer of health for the district, he describes an outbreak of enteric fever in the town, for the occurrence of which no very clear cause could be traced out by investigation. Mr. Spear has to rest content with the conclusion that there are conditions constantly at work in the locality which predispose the inhabitants to receive epidemic influences. As bearing upon the question of the alleged action of fumes from alkali works on certain zymotic diseases, it is not without interest to learn that in the infected quarter there exists a chemical factory giving off large quantities of chlorine and other gases, and that the streets which suffered most severely from the fever were those most exposed to the fumes. Four cases of typhoid were observed among the operatives themselves. A rather serious outbreak of diphtheria also occurred in the early part of the year. Mr. Spear winds up his report by specifying certain measures which should be carried out by the sanitary authority.

NOT a single death from small-pox was registered last week among more than six millions of persons living in sixteen of the largest English towns. The only fatal cases of this disease reported by the Registrar-General in his last weekly return were three in the city of Manchester and four in the borough of Salford. The prevalence and fatality of small-pox have recently increased in Manchester and Salford. Seventeen deaths were referred to this cause during the first nine months of this year, and since the end of September twenty-six other fatal cases have been recorded, including seventeen in the four weeks ending 18th inst.

IT is rumoured that H.M.S. *Grampus*, now used as a powder depôt at Portsmouth, is to be converted into a naval prison hulk. If this idea is carried out, great care should be exercised by the Admiralty in fitting this ship for such a purpose. Floating establishments at fixed moorings are not specially healthy, and the convict hulks moored off Woolwich some years ago were no exception to the rule.

DR. A. M. BUCHANAN lately delivered an address before the Andersonian University Medical Society, Glasgow, on the subject of "Free Trade in Medical Teaching." We have already stated that the lectures of one of the teachers at this institution would in future qualify for graduation in the University of Glasgow, and Dr. Buchanan enlarged on the benefits likely to accrue from such a liberal concession, and expressed a hope that the same privilege would be extended to every individual teacher at the Andersonian. He believed that the effect of the recognition of an extramural school upon the University of Glasgow would act as a stimulus to its professors. At the same time, unlimited free trade in medical teaching was strongly and pointedly deprecated.

IN London 1834 deaths were registered last week, including 68 from measles, 107 from scarlet fever, 8 from diphtheria, 88 from whooping-cough, 24 from different forms of fever, 15 from diarrhœa, 1 from varicella, and 514 from diseases of the respiratory organs. Of the fatal cases of fever twelve were referred to puerperal fever. Although in many of our large industries there are conditions strongly inimical to health, it is not often that we find a death recorded as directly due to the work. Last week the death of a woman in Limehouse was certified by the coroner to be caused by "chronic inflammation of stomach, produced by arsenical poisoning through working in an emerald-green factory."

AT a recent examination of the Pharmaceutical Society a lady—Miss J. S. Clarke—was declared qualified to be registered as a pharmaceutical chemist. The initiative taken by Miss Clarke will most probably be quickly followed, and the Society may expect a considerable influx of female students at its premises in Bloomsbury-square. A most praiseworthy determination is evinced by the Society to maintain a high standard of knowledge on the part of English pharmaceutists, as will appear from a report of an examination held this month, when out of forty candidates twenty-three were rejected.

WE learn from a contemporary that the ship *Borrowdale* arrived at San Francisco in the month of November with several cases of scurvy on board, and that until the British Consul intervened several men suffering from other diseases were kept on board the ship, and more or less neglected. Ship-masters are often chary of incurring hospital expenses in a foreign port, so that the men are entirely dependent upon the activity and energy of the consul, to whom, as it appears, these cases were represented by the reporter of one of the local daily papers.

The Times states that the Local Board of Hampton Wick have been served with a summons for neglecting to prevent the sewage of the parish from entering the river Thames. The penalties incurred since the date of notice amount to £94,000. The conservators, however, have decided that the summons should stand over for a short time, and that in the meantime a deputation from the Board should be received.

THERE are now two typical cases of scurvy in the Seamen's Hospital at Greenwich under the care of Dr. Ralfe. This disease in an uncomplicated form is now comparatively rarely seen in London, and so we recommend students to go down to Greenwich and increase their clinical experience as to a malady that many have not seen at all, and with which very few are familiar.

THE latest life returns from India give an annual rate of mortality of thirty-five per thousand for Madras. Fifty deaths from cholera occurred in the city in one week.

AT a time when the attention of all Englishmen is directed to India, there is an opportuneness in the commencement of an illustrated history of our vast dependency by Messrs. Cassell, Petter, and Galpin, who are widely known for their popular educational publications. We have received Part I. of the history, which is an admirable production in every way, while the price at which it is sold brings it within the reach of all.

THE Paris Municipality has of late been very liberal to scientific institutions. The Faculty of Medicine has obtained a grant of £4000; the Faculty of Sciences, £3000; and £2000 has been voted to the Finishing Scientific School. A vote of £12,000 to the five higher scientific institutions of the department of the Seine was also adopted.

AN important omission has been discovered in the 116th Section of the Public Health Act. The word "butter" has been omitted among articles that may be seized and destroyed under a magistrate's order, if found to be unfit for food. So that bad butter may still be exposed for sale and sold with impunity.

THE profession will learn with much regret that the health of Sir George Burrows has been somewhat impaired of late. We sincerely trust, and so also will a host of friends, that his indisposition will be of but short duration.

NUMEROUS cases of varicella have lately occurred on board H.M. cadet ship *Britannia* moored off Dartmouth, and, according to the *Army and Navy Gazette*, the school has been broken up prematurely in consequence.

PRINCE LEOPOLD has intimated, through Dr. Poore, his intention of subscribing ten guineas annually to the funds of the Royal Infirmary for Children and Women, Waterloo-road, S.E.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN important meeting of the Council of the College of Surgeons was held on Monday, the 20th inst. The Report of the Committee on "Examinations in Anatomy and Physiology" was adopted, and the following fellows of the College were elected members of the Board of Examiners in Anatomy and Physiology for the membership and fellowship:—Mr. John Birkett; Mr. Holden, Mr. Savory, and Mr. Henry Power, of St. Bartholomew's; Mr. Cooper Forster, of Guy's; Mr. T. Holmes, of St. George's; Mr. John Wood, of King's College; Mr. G. Gascoyen, of St. Mary's; and Mr. Christopher Heath, of University College. It will be seen that five of the nine appointments to the Board of Examiners have been filled by gentlemen who were already members of the Court of Examiners in Surgery, two of these gentlemen being the senior surgeons at the two largest metropolitan hospitals. Whether this be consistent with the spirit and intention of the resolution that the Board of Examiners and the Court of Examiners should be separate is a question for future consideration. On the first blush it certainly appears undesirable that the majority of the members of examiners in Anatomy should be also examiners in Surgery, several of them being at the same time members of the Council. If this practice be recognised there is no reason why the members of the Court of Examiners should not all nominate themselves and secure their election to the Board of Examiners, and thus defeat the object of the measure.

At the same meeting a committee was appointed to consider and report on Mr. Marshall's scheme for the institution of a compulsory examination in Anatomy at the end of the first winter session, and also to consider a rider which has been added by Mr. Le Gros Clark respecting the desirability of changing the periods of Primary and Pass Examinations of the College. This committee is composed of Messrs. Hancock, Holden, Gay, Marshall, Baker, and Forster, and the President and Vice-Presidents. The decision which these gentlemen will arrive at will be looked forward to with interest.

The motion of Mr. Critchett—the medical women's advocate—respecting the advisability of admitting women to the examination for the certificate of qualification in Midwifery, was referred to the Standing Counsel, who will report on the legal position of the Council in the matter.

Sir James Paget stated that the bodies co-operating for a Conjoint Scheme had invited the co-operation of the Society of Apothecaries, and that that body had consented to send two representatives to the conference. We believe that the Council of the College of Surgeons has determined to adhere to its resolution of June respecting the appointment of examiners as an essential condition of co-operation in the Conjoint Scheme.

The report of the Court of Examiners on the report of the visitors from the General Medical Council on the College examinations and on the recommendations and opinions of the General Medical Council, and that on Mr. Quain's letter to the Council reporting the proceedings of the General Medical Council during their annual meeting in 1875, were read and adopted. Without going closely into the details of these reports, it may be remarked that while the Court of Examiners acquiesced in some of the opinions and recommendations of the visitors of the Medical Council, it has decided against others, and has pointed out several inaccuracies made by the visitors in their report. We are glad to find that the Court of Examiners is of opinion that the physiological part of the Primary Examination is at present defective, and that it is expedient that it should be extended. This, we trust, will be done at once. By chance there are on the new Board of Examiners two physiologists, and only two. With the exception of Mr. Savory and Mr. Power, both from St. Bartholomew's, there is no one on the Board who can conscientiously lay claim to more than a general knowledge of physiology. If it were not that Mr. Power's great experience as an examiner in physiology necessitated his election, it would be difficult to account for the presence of three St. Bartholomew's surgeons on the Board. It is, however, we believe, probable that when Mr. Holden has assured himself that the newly-elected examiners have shown themselves equal to their duties, he will resign his examinership in anatomy and physiology, and bestow on the Court of Examiners the benefit of his undivided services. Mr. Forster, the senior surgeon of Guy's, may be expected to take the same praiseworthy step. Mr. Savory's presence at the Board as a physiologist is indispensable, but we sincerely trust that either one more special examiner in physiology will be appointed, or that the first vacancies that arise will be filled by Fellows of the College who have had actual experience as teachers or examiners in physiology, and that the examination in this subject, both the written and *vivâ voce*, will henceforth be separate from that in anatomy.

With reference to the recommendations of the General Medical Council that an examination should be held at the College in Materia Medica and Chemistry, the Court of Examiners do not advise the addition of a special examination in these subjects.

THE BIRKENHEAD BOROUGH HOSPITAL.

To the Editor of The Lancet.

Sir,—It is sometimes a difficult thing strictly to define in small provincial hospitals the exact duties of the house-surgeons and of the matrons. But I think it will be apparent to everyone that the house-surgeons' duties ought to be, as much as possible, of a professional nature.

Some little time since, the Committee of the Birkenhead Borough Hospital decided that the house-surgeons should be compelled to keep accurate accounts of all things consumed in the kitchen—such as tea, sugar, potatoes, &c. Upon the Committee informing the senior house-surgeon of their decision, he calmly remonstrated with them upon the indignity which he would suffer in being compelled to perform the duties of a housekeeper. It was all, however, to no purpose, and he, of course, at once resigned his appointment.

Committees are not, as a rule, noted for courtesy to their medical officers, or for profound knowledge of the institutions which they govern; but it is, I think, rare to find even an irresponsible body of men so far forget themselves as to offer such an indignity to a member of the profession.

I am, Sir, your obedient servant,

December 9th, 1875. A Late House-Surgeon.

Obituary.

JAMES PART, M.D.

Dr. Part was born in the neighbourhood of Wigan (to which district his family belonged) in the year 1809. He served his apprenticeship to the medical profession with a Mr. Christopher Morris at Wigan. He came to London about 1830, and studied at St. Bartholomew's and University College Hospitals, and obtained the surgical prize for the year 1830–31 of the Medical School in Aldersgate-street. He was L.S.A. 1832, M.R.C.S. 1832, F.R.C.S. 1854, M.D. St. Andrews 1860.

He commenced his medical practice as house-surgeon to the Wigan Dispensary, but shortly after settled in London, where he became Surgeon of the Artists' Annuity Fund Society, and was for a time President of the North London Medical Society.

He was author of the Medical and Surgical Pocket Casebook, and contributed various papers on medical and anatomical subjects to The Lancet and the Transactions of the Pathological Society, and other publications. He also delivered various lectures, and notably a course devoted to the anatomy of expression, with copious diagrams.

As a professional man, he gained the high esteem and confidence of his brother practitioners, as well as of the large circle of patients to whom his professional skill was of service. He was twice married, and leaves by his first wife five children surviving him.

JAMES TUCKER, M.D.

We regret to announce the death of Dr. James Tucker, which sad event took place at his residence in Sligo, on the 1st of October. Dr. Tucker had for many years past been one of the leading sanitarians in the west of Ireland, and as officer of health for the borough of Sligo did good service to the community. His efforts to promote the sanitary welfare of the people, and so to prevent disease, were unceasing. The members of the profession to which he belonged have also cause to remember him, for he was ever foremost in endeavouring to promote their welfare. He was author of Essays on Cholera and Fever, Public Health, &c., as well as of a pamphlet lately written, entitled "Light and Scenery: Thoughts on Health." So highly were his investigations on those subjects thought of, that he was commissioned by the Irish Government to examine and report on the English cattle plague of 1866. Dr. Tucker was surgeon to the Sligo Rifles, and held many other appointments, the duties of which he attended until a week before his death, in the 63rd year of his age.

Medical News.

Royal College of Physicians of London.—At a meeting of the College on Dec. 20th the following gentlemen were admitted Licentiates:—

Atkinson, Francis Edward, Regent-square.
Bartlett, Henry, Great Dover-street.
Barton, James Kingston, Doughty-street.
Birch, Philip, Lichfield.
Cadge, William Hotson, Woburn-place.
Cobb, Robert, St. Bartholomew's Hospital, Chatham.
Crétin, Eugène, M.B. Lond., St. Bartholomew's Hospital.
Foley, Samuel, St. David's.
Harper, Robert Russell, Holbeach.
Hastings, George, M.D. Brussels, St. Bartholomew's Hospital.
Hawkins, Alexander Frederick, Regent-square.
Miller, Frederick Daniel, Angles-road.
Morris, Henry, Wickham.
Morris, William Whitehead, East Bridgford.
Richardson, Timothy, Commercial-road.
Sheehy, William Henry Patmore, St. Bartholomew's Hospital.
Smalley, Herbert, East Thurrock, Grays.
Strugnell, Frederick William, Queen Charlotte's Hospital.
Verco, Joseph Cooke, M.B. Lond., Ovington-street.

Royal College of Surgeons of England.—At a meeting of the Council held on the 20th inst., the following Members, who passed the examination for the Fellowship on the 25th, 26th, and 27th of November, were duly admitted Fellows of the College:—

Barrow, Albert Boyce, Newmarket.
Garton, William, L.S.A., St. Helens, Lancashire.
Jacobson, Walter Hamilton A., M.B. Oxon., Guy's Hospital.
Jones, Thomas, M.B. Lond., Manchester.
Law, William Thomas, M.B. Ed., Seamen's Hospital, Greenwich.
Lyell, Robert Wishart, M.D. Lond., Penge, Surrey.
Mackenzie, Lewis, L.R.C.P. Lond., Tiverton, Devon.
Winterbottom, Augustus, Sloane-street, Chelsea.

Six candidates, having failed to satisfy the Court of Examiners, were referred for twelve months' further professional study.

The following Members of the College were elected Fellows:—

Bratton, James, L.S.A., Shrewsbury; diploma of membership dated May, 1836.
Spong, William Nash, L.S.A., Faversham; Aug. 1842.

The election of an Examiner in Medicine in the vacancy occasioned by the resignation of Dr. Wilks will take place at the meeting of the Council in January next.

Apothecaries' Hall.—The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on Dec. 16th:—

Buckell, Ernest Hook, University College Hospital.
Haselden, Robert, Bolton, Lancashire.
Macintire, John Henry Lee, Gower-street.
Reeve, Henry, Victoria-park, Hackney.
Richardson, Arthur, Rusholme, Lancashire.

The following gentlemen passed the Primary Professional Examination on the same day:—

Charles Gerald Dalton, London Hospital; John Morgan, Guy's Hospital; Edward Thurlow Prior, William Bradshaw Rigby, and Francis George Herbert Whitley, St. Bartholomew's Hospital; Charles Wm. Ebenezer Gay, Ernest Oliver Scallon, John Symons, William Arthur Stephenson Walsh, and William Robert White, King's College.

Dr. William Matterson, has been placed on the Commission of the Peace for the city of York.

On December 20th, a handsome clock, with a suitable inscription, was presented to Mrs. Puddington, the Matron of the London Fever Hospital, by the members of the Committee of that institution, in the presence of all the nurses and officers.

BOOKS ETC. RECEIVED.

Dr. Carpenter's Physiology.
Dr. Dalton's Human Physiology.
Dr. Ridge: Diet for the Sick.
Cholera Epidemic of 1873 in the United States of America. Vols. I. and II.
Dr. Billroth: Uber das Lehren und Lernen der Medicinischen Wissenschaften.
A Biennial Retrospect of Medicine and Surgery, 1873–74.
Mr. Hutchinson's Catalogue of Skin Diseases.
Mr. Stigand: Life, Work, and Opinions of Heinrich Heine. Vols. I. and II.
Mr. Benson: Time and Time Tellers.
Mr. Haviland's Geography of Heart Disease, Cancer, and Phthisis.
Year-book of Pharmacy, and Transactions of the British Pharmacy Conference.
The Indian Alps. By a Lady Pioneer.
The Poems of Sir Walter Scott, Bart.
M. de Chaumont: Lectures on State Medicine.

Medical Appointments.

Bain, D. S. E., F.R.C.S.Ed., has been appointed Medical Officer for the Sellinge District of the Elham Union, Kent, vice E. J. Kent, resigned.

Brookfield, J. S., M.D., M.R.C.S.E., has been appointed Medical Officer of Health for the Clayton West and Gunthwaite and Ingbirchworth Urban Sanitary Districts, and the High Hoyland Sub-district of the Penistone Rural Sanitary District.

Clarke, F. W., M.R.C.S.E., has been reappointed a Surgeon to Sir John James's Charity, Bury St. Edmund's.

Cooke, W. C., M.R.C.S.E., has been appointed Resident Medical Officer to the St. Pancras and Northern Dispensary, vice Cross, resigned.

Dick, J., M.D., L.R.C.P.Ed., L.M., has been appointed Medical Officer and Public Vaccinator for the Harrington District of the Whitehaven Union, vice Dixon, resigned.

Hichens, J. S., M.R.C.S.E., has been appointed Medical Officer of Health for the Redruth Urban Sanitary District.

Hinnell, G. J., M.R.C.S.E., has been reappointed a Surgeon to Sir John James's Charity, Bury St. Edmund's.

Mawson, T. W., M.B., C.M., has been appointed Medical Officer for the Messingham District of the Glanford Brigg Union, Lincolnshire, vice Richardson, resigned.

Morris, D. W., L.K.Q.C.P.I., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Skenfrith District of the Monmouth Union, vice Lane, resigned.

Pattinson, Mr. J., has been appointed Public Analyst for South Shields: £25 per annum, and 7*s.* 6*d.* per analysis.

Peirce, J. E., M.R.C.S.E., has been appointed Medical Officer to the Redditch and District Medical Aid Association, vice Draper, resigned.

Rowland, J. D., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Western Division of the Tralee Dispensary District of the Tralee Union, vice Lawlor, resigned.

Sidey, J. A., M.D., L.R.C.S.Ed., has been appointed Medical Officer to the Edinburgh County Prison, vice Simson, resigned.

Traill, H. S., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the No. 7 District of the South Molton Union, vice Ford, resigned.

Turner, J. E., L.R.C.P.Ed., L.R.C.S.Ed., L.M., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Tuam No. 2 Division of the Tuam Dispensary District of the Tuam Union, Co. Galway, vice Dwyer, deceased.

Van, A. F., M.R.C.S.E., has been appointed Medical Officer of Health for the Cranborne Sub-district of the Wimborne and Cranborne Rural Sanitary District, vice Underhay, resigned.

Wacher, F., M.R.C.S.E., has been appointed Medical Officer for the Sturry District of the Blean Union, Kent, vice Jameson, deceased.

Walker, H. E., M.D., L.K.Q.C.P.I., has been appointed Medical Officer and Public Vaccinator for the Whitwell District of the Worksop Union, vice Kenny, resigned.

Watson, A. M., M.D., M.R.C.S.E., has been appointed Medical Officer of Health for the Penistone Urban Sanitary District, and the Townships of Langsett and Oxspring and the rural part of the Township of Hunshelf in the Penistone Rural Sanitary District.

White, J. C., L.R.C.P.Ed., M.R.C.S.E., has been appointed Resident House-Surgeon to the Ardwick and Ancoats Dispensary, Manchester, vice Pearse, resigned.

Wilson, J., L.R.C.P.Ed., L.F.P. & S. Glas., has been appointed Medical Officer of Health for the Stockton Rural Sanitary District: £200 per annum.

Births, Marriages, and Deaths.

BIRTHS.

Etheridge.—On the 19th inst., at Seasalter, Whitstable, the wife of Chas. Etheridge, M.R.C.S.E., of a son.

Longhurst.—On the 17th inst., at Witham, the wife of Dr. Longhurst, late 60th Rifles, of a son.

Ogle.—On the 15th inst., at The Elms, Derby, the wife of W. Ogle, M.D., of a son.

Will.—On the 20th inst., at Sheerness, the wife of George Elmsly Will, Surgeon-Major Army Medical Department, of a daughter (Mildred Agnes).

MARRIAGES.

Denham—Barclay.—On the 2nd ult., at St. Paul's Presbyterian Church, Bayswater, John Denham, M.D., to Louise, widow of Captain Barclay.

Moss—Downing.—On the 14th inst., at St. Peter's, Dublin, Herbert Campbell Moss, M.B., to Mary Elizabeth, daughter of A. M. Downing, Esq.

DEATHS.

Andrew.—On the 12th inst., at Northampton, Henry Andrew, F.R.C.S.E., of Truro, aged 60.

Beaumont.—On the 12th of Oct., at Toronto, Wm. Rawlins Beaumont, M.D.

Bourne.—On the 14th inst., at Old Brompton, M. W. Bourne, M.D., aged 51.

Carleton.—On the 16th inst., at Russell-place, Dublin, D. J. Carleton, L.K.Q.C.P.I., aged 30.

Daniell.—On the 6th inst., W. C. Daniell, M.R.C.S.E., of Calverton Limes, Stony Stratford, Bucks, aged 40.

Reid.—On the 25th ult., at Bowmanville, Ontario, Canada, H. R. Reid, M.D.

Smith.—On the 9th inst., at Ventnor, H. C. Smith, M.R.C.S.E., of Maidstone, aged 34.

Squarey.—On the 12th inst., at Brighton, Dr. C. E. Squarey, late of Upper Wimpole-street, aged 32.

Sutherland.—On the 12th inst., at Thurso, Robt. Sutherland, L.R.C.P.Ed., Staff Assistant-Surgeon, on half-pay.

White.—On the 12th inst., at Penrhos, near Carnarvon, Dr. Wm. White, retired Surgeon-Major Bengal Army, aged 58.

[N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*]

Notes, Short Comments, and Answers to Correspondents.

THE LANCET COMMISSION ON LUNATIC ASYLUMS.

The Report of The Lancet Sanitary Commission on Colney Hatch Lunatic Asylum will appear next week, Jan. 1st, 1876.

Traction on Ligatures.

M. Boeckel, of Strasburg, has published an article in the *Bull. de Thérap.* (Dec. 15th, 1875), on the well-known system of continuous traction in the treatment of fractures, white swelling of the knee, &c. He is a great advocate of this mode of treatment in appropriate cases, and throws out the hint that it might be used with advantage to get rid of ligatures which are too long in coming away. The author considers that, as early as the eighth day, means should be used to detach the ligature, and he advises to tie a string to the latter, and to connect with it a weight of between one and three ounces. In this way he succeeded, in about twelve hours, with ligatures of the carotid and other large vessels. He holds that in a few days, when the ligature is not interfered with, it is reduced to a mere loop, which no longer exercises any constriction. If this were quite true, the least traction with the hand should carry it away. M. Boeckel closes by saying that continuous traction of ligatures should, as a rule, be begun after the eighth day as long as catgut, acu- or forci-pressure (and he might have said torsion) have not abolished the use of ligatures altogether.

The Treatment of Ringworm.

To the Editor of The Lancet.

Sir,—In your issue of the 11th inst. I observe the letter of Dr. J. F. Brice on this subject. I received my copy of The Lancet too late to be able to reply last week. I would point out to Dr. Brice that, according to his own statement, he has not followed my plan of treatment. I use the iodine for three days. He *persistently* applies it for five weeks. There is such a thing as doing more than curing the disease—viz., causing another. This I have frequently seen in the case of itch treated with sulphur ointment, where the ointment has been too long employed, and so with iodine in ringworm. When I first used it, I was in doubts about the appearance at the end of the week, as the disease was still perceptible, although it did not spread. What I would suggest to Dr. Brice is, that he try it again, using the iodine two or three times, and then wait, when he will find the spots will scale off.

Your obedient servant,
Kinghorn, Dec. 21st, 1875. Jas. Welsh, M.D.

To the Editor of The Lancet.

Sir,—In case petroleum fails, I would advise your correspondent to try a solution of perchloride of mercury in rectified spirits of wine (one scruple to the ounce). It should be applied with a camel-hair brush, and repeated if the first application fails in arresting the progress of the disease. It generally blisters the part slightly. I have never known it fail.

Your obedient servant,
Sibford, Banbury, Dec. 11th, 1875. F. L. Milburn.

To the Editor of The Lancet.

Sir,—Will you allow me to ask Dr. Brice to try *pure* liquid carbolic acid on his obstinate case of ringworm? I tried it while with Mr. Bishop, of Tonbridge, in several cases, and never knew it to fail. Smear some oil outside the ringworm, then paint the worm with the pure acid by means of a brush, and allow it to dry. Yours truly,
Greenhithe, Dec. 15th, 1875. Edwin Tipple, L.R.C.P. Ed., &c.

Medical Advertising in the Colonies.

This system is painfully prevalent in New South Wales. More than two columns of the *Miner's Advocate* is taken up with advertisements of the testimonials of John Harris, M.B., C.M., L.R.C.S.E., L.R.C.P.E., L.M. R.C.S. & P.E. Mr. Harris does not display so much taste as might be hoped for in one with so many letters after his name. The columns are occupied with testimonials from John Struthers, M.D.; John Macrobin, M.D.; Alexander Harvey, M.D.; William Pirrie, M.D., &c. &c., all testifying that Mr. Harris is a promising young man. If this use is to be made of testimonials, those teachers who write them so freely will have to consider whether they do right in so doing, or they will have to insert in large letters in their testimonials—"Not to be used as puffs."

Professor Dittel's Advice in Enlarged Prostate.

If our readers will refer to page 900 of last week's number of The Lancet, they will see that the professor thinks puncture of the bladder in the hypogastrium, and the permanent escape of urine through an apparatus, preferable to battling with the enlarged prostate and the consequent evils. We did not for a moment think that Prof. Dittel was the originator of the method, and wished simply to put upon record that such was his view of the subject. The Viennese surgeon had been forestalled, as evidenced by a passage in a lecture of Sir Henry Thompson's, published in this journal (The Lancet, Jan. 2nd, 1875).

Mr. John Taylor, (Sheffield.)—A parliamentary paper was published on the subject on the occasion of the last debate in the House of Commons, and might probably be obtained on application to Hansard, Great Queen-street.

Dr. J. Bell Pettigrew is thanked, but we have already noticed the fact.

The Residence Condition of British Medical Graduation.

To the Editor of The Lancet.

Sir,—Without trespassing much on your space in reference to the letter of "Omega" in your issue of Dec. 11th, I assert that the question, "How is it that registered medical practitioners in this country cannot obtain degrees at home without residence?" is one of the greatest importance to the well-being of the profession, and the unanimity which should pervade it. But I cannot look upon the statements of your correspondent as to the iniquitous combination of the Universities, and their degrees being reserved for youths, whose time is valueless, and best employed in useless residence, without experience, and with a store of theoretical knowledge got up for the occasion, as other than, to say the least, equally inconsiderate and unjust. I think that any rational medical man will say that youth is the time of greatest value in the medical profession, and even a child is taught the value of time when young; and, in regard to University teaching, it is now universally acknowledged to be eminently practical, not only in the truly professional branches, but in the collateral sciences, a theoretical knowledge of which is also necessary to form the basis for the acquirement and cultivation of medical knowledge, and not to vanish as quickly as learned; and, until "Omega" alters his opinion, I doubt if he would be a fit recipient of their degrees. However, the cart is sometimes put before the horse; and if, after several years' practice, a hard-working man is willing to be submitted to examination for a doctor's degree at home, rather than obtain a foreign one, and finds himself unable to keep the period of residence exacted from risk to his practice or unwillingness from his position, is it not sad that he cannot have an opportunity of doing so? Could the examining University of the kingdom, granting other degrees without residence, not initiate, and extend its sphere of usefulness to such as "Omega"?

Yours truly,
Dec. 13th, 1875. Alpha.

To the Editor of The Lancet.

Sir,—In common with many others, I am in much the same situation as "Omega," whose letter appears in your issue of Dec. 11th. Like him, I have taken every pains to keep myself well read in every branch of my profession since I have been in practice, and am willing to submit to (and I believe am able to undergo) any examination to obtain the M.D. degree at a British University; but such is the obstinacy with which these institutions insist upon residence that I am unable to obtain the degree in this country. I would ask, Is a man who at twenty-three or twenty-four years of age obtains his diploma or degree supposed to have acquired all knowledge respecting our science and art? Is it not possible for him to acquire a vast amount of the most important information after he has left his school? And yet, whatever his knowledge, experience, and skill may be, he has no opportunity of obtaining a degree in medicine, and he has no incentive whatever to keep up the knowledge he acquired when a student. I submit that, were a man able to obtain a degree after he has been five or six years in practice, without residence, it would be a great encouragement to him to keep up his knowledge.

Respecting foreign degrees, I myself thought of going to Brussels to be examined during the past autumn; but the knowledge that my professional brethren would certainly say that my degree was *but* a foreign one (and perhaps my other qualifications also) induced me before doing so to write several letters to the University of Durham on the matter, and the answers I received were such as to lead me to suppose that its governing body were contemplating throwing open its degrees to qualified men, which I venture to hope may be the case, although I have heard nothing since to confirm my hopes, and the regulations published in the Students' Number of The Lancet are the same as they were last year. I cannot, however, but think that some University will before long see the matter in the right light, and throw open its doors. Cambridge has in the subject of State Medicine, and surely some other University might follow its example by doing the same in the larger and more important subject of medicine generally.

I am, Sir, your obedient servant,
Dec. 14th, 1875. L.R.C.P. Lond.

P.S.—I have often thought, if the profession petitioned some University, it might have the desired effect.

To the Editor of The Lancet.

Sir,—"Omega," whose letter you published in your issue of the 11th inst., states a hard case. Mine is, I think, harder. The misconduct of a brother M.D. whom I rescued from ruin, conjoined with that of a clergyman into whose family I married, has hurled me from riches to comparative poverty, from strength to weakness. Possessing as I do a natural aptitude for imparting knowledge, I could, without doubt, make a fair income as a schoolmaster, provided only I could obtain a respectable B.A. I am already a medical graduate of a Scotch University, yet even my *alma mater* is forbidden by law to grant me a title in Arts unless I undergo a two years' residence. I have a wife and three children, and am forty-one years of age. How can I sacrifice both time and money? Why should not Durham—a University in need, I am informed, of both occupation and funds—be empowered to grant degrees of all kinds to middle-aged men after examination, but without residence? Can you assist us, Mr. Editor?

I remain, Sir, yours truly,
Dec. 12th, 1875. M.D., M.R.C.S., L.S.A.

Treatment of Lipoma.

Dr. Hasse, of Nordhausen, injects these tumours with alcohol. A certain amount of the latter should be made to enter the fatty growth through several apertures, allowing some days to intervene between each injection. The tumour then softens and fluctuates; and the operator should at that period incise the growth and empty it, by means of gentle pressure, of the oily liquid which has been formed. Febrile reaction is generally very slight. It is hardly worth while in some fatty tumours to subject the patient to numerous punctures and injections, which may be more or less painful, and crown all by an incision and kneading of the tumour. In very large lipomatous growths, where enucleation leaves a deep cavity, which is sometimes a long time in healing, and where the incision must be large, and the tearing out requires a certain amount of force and manipulation, Dr. Hasse's system may perhaps be applicable, especially with timid patients.

A Good Almanac.

The British Almanac of the Society for the Diffusion of Useful Knowledge for 1876, published by the London Stationers' Company, is a well-known publication, containing about as good a shilling's worth of useful information—some of which cannot be obtained elsewhere—as can well be expected.

Indignans.—We entirely agree with our correspondent. "Indignans" should send the bill to the President of the College whose diploma is held by the person in question.

Commune Bonum should authenticate his communication.

Certificates of Still-birth.

To the Editor of The Lancet.

Sir,—Would you kindly enlighten me whether it is compulsory to give a certificate for the burial of a miscarriage. I am not aware of any rule. The ordinary certificate of death cannot, I think, refer to abortions. In this case the certificate is given to the sexton, the registrar refusing to have anything to do with the registration of still-born infants.

I am, Sir, yours &c.,
Silloth, December, 1875. J. Leitch.

⁂ Under the 18th section of the Births and Deaths Registration Act, 1874, it is provided that no still-born child shall be buried in any burial-ground without the production of, either (*a*) a written certificate that such child was not born alive, signed by a registered medical practitioner who was in attendance at the birth, or who has examined the body of such child; or (*b*) declaration signed by some person who would, if the child had been born alive, have been required by this Act to give information concerning the birth, to the effect that no registered medical practitioner was present at the birth, or that his certificate cannot be obtained, and that the child was not born alive; or (*c*), if there has been an inquest, an order of the coroner. The Act contains no clause making it *compulsory* upon the medical practitioner to give a certificate of still-birth, and indeed especially provides for the production of a declaration to the same effect in cases where a medical practitioner is from any cause unwilling or unable to give the required certificate.—Ed. L.

Centenarians.

There is always some doubt respecting these, and often the simplest documents are wanting to place the real age on a secure basis. A very interesting little book on this subject has just been published, called "Recherches sur les Centenaires nés ou morts dans le Département de la Marne," by Amédée Lhote. This department appears favourable to the threading out of numerous years, as there centenarians are not scarce. Some verses are scattered in the book, among which we notice the following epitaph quoted by *L'Union Médicale*, Nov. 27th, 1875:—

> "Ci gît Paul, qui, docile à cet avis du sage :
> Dans tout ce que tu fais, hâte-toi lentement ;
> Pour gagner l'autre monde, alla tout doucement ;
> Et mit cent ans entiers à faire le voyage."

C. K. W.—1. Only in very urgent circumstances would it be right to do so.—2. It would be an act of pure good nature to do so.—3. It would be a reason for being dissatisfied with that surgeon.

M.D.—We have unfortunately not kept the particulars of the case referred to.

Unfortunate Catheterism.

Some time ago we alluded to a case of death after catheterism which occurred at Bordeaux. A pharmacien, very fond of prescribing and operating, had been applied to in a case of retention. He sent his son to relieve the patient, and the instrument was so used that the latter died soon after the operation. The affair was lately before a French Court, and the young pharmacien was sentenced to ten days' imprisonment for wounding through carelessness, and fined £1 16*s*. for illegally practising medicine.

A Correction.

To the Editor of The Lancet.

Sir,—In the excellent report of the proceedings of the Clinical Society on the 10th inst., in your issue of to-day, I observe an error and an omission in reference to the case of the carpenter (not carman) whom I exhibited at the meeting, both of which are important, clinically considered. These are—first, the patient suffered severe symptoms of diabetes *three months* instead of six weeks, as stated; and secondly, he lost 3 st. 8 lb. in weight before being placed under treatment—a fact attesting the severity of the disease.

Yours truly,
Wimpole-street, Dec. 18th, 1875. A. Scott Donkin, M.D.

Another Medical Victim.

The public at large have no conception of the number of medical men who die from contagious diseases caught in the practice of their perilous profession; nay, many of them perish at the threshold of their career whilst being employed as dressers in hospitals. At Paris, quite lately, a student of the Children's Hospital (Ste. Eugénie), named Gary, died of diphtheria whilst attending little patients affected with that destructive complaint. At the beginning of this year another student, named Vallerian, was carried off by small-pox at the temporary hospital erected for the reception of variolous patients; and shortly afterwards M. Gipoulon fell a victim to diphtheria, the germ of which had been taken in hospital.

Tyro's complaint is a little too vague. If he will furnish us with definite facts or cases in illustration, we shall be glad to give him our opinion.

Mr. Alfred Cresswell's letter shall appear next week.

Cheap Doctoring.

To the Editor of The Lancet.

Sir,—My attention has been attracted by your remarks (Oct. 30th), in answer to "S.," on the "cheap" system of attending and supplying poor persons with medicines, and the question of the "possibility of supplying proper medicines on such terms."

In the early part of my professional life I was one of the medical officers to the Christ Church, to the St. George's, and to the All Saints Church Provident Societies in Birmingham. To the first, all the medical officers attended gratuitously, but did not supply medicines. The medical officers to the two other Societies agreed to supply the medicines, and to be paid at a low rate for their attendance, with the exception of myself; but I was so urgently pressed to attend on the same terms as the other medical officers that I consented to do so for one quarter. Accordingly I made an arrangement with a respectable druggist, whose shop was conveniently situated, to dispense for such of my patients as belonged to the Society. On explaining to him the circumstances of the case, he readily undertook to do the dispensing, charging the *cost* price only for the drugs, and five per cent. for his trouble. At the end of the quarter I had to pay him about £1 12*s.* over and above what I received from the Society for my quarter's attendance.

I also attended gratuitously a dispensary, established in a populous neighbourhood, on the self-supporting system; but although there were many honorary subscribers, it had to be closed after a few years, because it could not pay its expenses, and this was owing to the great difficulty of collecting the subscription of one penny weekly from each self-supporting member.

After the experience I had for several years, I cannot understand how "S." can make the "cheap" system pay him. In my opinion it is better for the "doctor" to *give* his advice to such of his poor neighbours who cannot afford to pay him, and let them obtain the medicines themselves.

Your obedient servant,
Francis Elkington, M.D.,
Formerly of Birmingham, England.
Brockville, Ontario, Nov. 16th, 1875.

Punch's Pocket-Book for 1876.

In addition to illustrations by Tenniel, Charles Keene, and Linley Sambourne, with much light amusing matter, Punch's Pocket-Book contains the calendar, cash account, diary, and daily memoranda that go to make up the ordinary almanacs.

L. E.—In estimating the population of a town or district, it is generally assumed, failing a more reliable basis for calculation, that the *rate of increase* which prevailed between the last two census enumerations has since been maintained. In the case of Shardlow district we know that the population was 31,113 in 1861, and 33,925 in 1871; from these numbers first find the annual (geometrical) rate of increase in the ten years, and the addition of four and a quarter to this rate to the number in 1871 will give the estimated population in the middle of the year 1875. Very few annual reports of medical officers of health can be obtained, except on application to medical officers of health or sanitary authorities.

The Keighley Union.

To the Editor of The Lancet.

Sir,—I am very much astonished that upon the *ipse dixit* of a local paper you should charge me with receiving my instructions as to the treatment of my pauper patients from the guardians. There is not one of the guardians who has ever in any way whatever suggested to me how I should treat my patients. Knowing the benefits which my private patients receive from a modified water treatment, both hot and cold, I asked the guardians to find me the requisite means, that I might treat my pauper patients as I thought would soonest lead to their recovery, and to pay some person to give to them baths, or wet packs, or whatever else I might deem necessary. I need not quote to you or the profession the names of the leading physicians both in England and on the Continent who use this treatment with marked success. I certainly think that it is due to me for you to place this disclaimer in as prominent a place as your own article.

I am, Sir, your obedient servant,
Arthur Roberts,
Medical Officer of the North Keighley Union.
Keighley, Dec. 21st, 1875.

*** It is a pity that the Chairman of the Board, in noticing the matter, did not state that the first overture on the subject was from the medical officer. We have, of course, no objection to offer to Mr. Roberts treating his patients in the way which seems to him best.—Ed. L.

A. M. D., (Dover.)—The remarks referred to were made by Dr. Little, Professor of Medicine, at the opening of the Royal College of Surgeons, Ireland, and they strike us as among the best and most judicious remarks that we have read for some time.

The new Dean of the Paris Faculty.

Professor Vulpian is finally installed in this office. This was done with a certain amount of ceremonial, during which highly complimentary speeches were addressed to M. Wurtz, the late Dean, the efficient manner in which he had performed his difficult task being eulogistically acknowledged. It should be remembered that in France the Dean is virtually the chief of the school, that he has vast powers, and that his office is in no way analogous to that of the Deans of our own medical schools.

Communications not noticed in the current number will receive attention in our issue of the ensuing week.

Communications, Letters, &c., have been received from—Sir Jas. Paget, Bart., London; Sir Thomas Watson, Bart.; Sir W. W. Gull, Bart.; Dr. Brown-Séquard, Paris; Sir H. Thompson, London; Prof. Rolleston, Oxford; Dr. R. Barnes, London; Dr. Maudsley, London; Mr. Pollock, London; Dr. Geo. Johnson, London; Dr. Hughlings Jackson, London; Prof. Laycock, Edinburgh; Dr. Donkin, London; Mr. Maunder, London; Mr. Holthouse, London; Mr. John Wood, London; Dr. Langdon Down, London; Mr. Henry Smith, London; Mr. Adams, London; Dr. B. Hicks, London; Mr. Barwell, London; Prof. Spence, Edinburgh; Dr. Pettigrew, St. Andrews; Dr. Wilson Fox, London; Mr. C. De Morgan, London; Dr. Broadbent, London; Mr. Sidney Jones, London; Dr. C. LECTURES, ETC.

BARNES, Dr. R.:
  Clinical Lectures on the Rectum and Anus in their relations to Ovarian, Uterine, and Perimetric Diseases.
    Lecture IV., 119
  Introductory Address delivered at St. George's Hospital, Oct. 1st, 1875, 473
BEGBIE, Dr. J. W.:
  Address in Medicine, delivered before the Annual Meeting of the British Medical Association, at Edinburgh, in August, 1875.
    Ancient and Modern Practice of Medicine, 191
BROADBENT, Dr. W. H.:
  Clinical Lectures on the Pulse: its Diagnostic, Prognostic, and Therapeutic Indications. Delivered at St. Mary's Hospital in the Summer Session of 1875, 441, 549, 583, 901

Bryant, Mr. T.:
  Introductory Address to a Course of Lectures on the Principles and Practice of Surgery. Delivered on Oct. 5th, 1875, 725
Buchanan, Dr. G.:
  Introductory Lecture (Abstract of an) delivered at Glasgow University at the Opening of the Medical Session 1875-6, 654
Curnow, Dr. J.:
  Introductory Lecture on Medical Education; its Spirit and its Method. Delivered at King's College, on Oct. 1st, 1875, 476
Fox, Dr. T.:
  Clinical Lecture on Feigned "Erythema Gangrenosum" (a Case of Malingering). Delivered at University College Hospital, 617
Humphry, Dr. G. M.:
  Address on Medical Study and Examinations. Delivered at the Liverpool School of Medicine, 550
Hewitt, Dr. G.:
  Clinical Lecture on Convulsions due to Morbid Conditions of the Uterus in the Non-puerperal State. Delivered in University College Hospital, 199
Hill, Mr. B.:
  Clinical Remarks on Tapping and Draining the Pleura. Delivered in University College Hospital, 87
Hutchinson, Mr. J.:
  Clinical Lecture on Soft Chancres in their relation to Syphilis, 409, 444
Jackson, Dr. J. H.:
  A Lecture on Softening of the Brain, 335
Johnson, Dr. G.:
  Lectures on some Nervous Disorders that result from Overwork and Mental Anxiety.
    Lecture I., 85
    Lecture II., 155
    Lecture III., 651
Lee, Mr. H.:
  Hunterian Lectures on Syphilis, and on some Local Diseases affecting principally the Organs of Generation. Delivered at the Royal College of Surgeons of England.
    Introduction: Inoculation of Syphilitic Blood, 121, 157
    Treatment of Syphilis, 235, 267
Lund, Mr. E.:
  Introductory Address on Science in Surgery. Delivered at the Owens College (Manchester Royal) School of Medicine, Oct. 4th, 1875, 515
Macleod, Dr. G. H. B.:
  Introductory Lecture to the Winter Course of Clinical Surgery. Delivered at the Western Infirmary of Glasgow (University Clinic), 760
Maunder, Mr. C. F.:
  Lettsomian Lectures on the Surgery of the Arteries. (Illustrated by 27 Operations of Ligature by the Author, and other Cases of Disease and Injury.) Delivered before the Medical Society of London, Jan. 1875.
    Lecture III.—On Ligature of a Main Artery to Arrest Acute Traumatic Inflammation, 1, 43
Rutherford, Dr. W.:
  Address (Abstract of the) in Physiology, delivered before the Annual Meeting of the British Medical Association, at Edinburgh, August, 1875.
    The Vivisection Question, 238
Savory, Mr. W. S.:
  Clinical Lecture on a Case of Ecchymosis of the Scrotum. Delivered at St. Bartholomew's Hospital, 691
Spence, Mr. J.:
  Address (Abstract of the) in Surgery, delivered before the Annual Meeting of the British Medical Association, at Edinburgh, August, 1875, 239
Thompson, Dr. H.:
  Clinical Lecture (Abstract of a) on a Case of Syphilitic Disease of the Liver, with peculiar Physical Signs in the Abdomen, 301
Thompson, Sir H.:
  Lecture (Part of a) Introductory to the Course given at University College Hospital. Delivered on Nov. 15th, 1875, 759
  A Clinical Lecture on Diagnosis, delivered at University College Hospital on Nov. 18th, 1875, 793
  A Clinical Lecture on the Physical Examination of the Urethra in Cases of Stricture. Delivered at University College Hospital on Nov. 18th, 1875, 827
  A Clinical Lecture on the best manner of employing Instruments in Cases of Stricture where much difficulty exists. Delivered at University College on Nov. 25th, 1875, 867
Lee, Dr. R. J., the cutaneous eruption sometimes following vaccination, 265

MIRROR OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Birmingham and Midland Hospital for Women.—Saccular dilatation of the urethra; removal; cure, 625—Removal of a large soft fibro-myoma by abdominal section; death, ib.—Cases of ovarian tumour simulating extra-uterine pregnancy, with complete extrusion of uterus and bladder; successful ovariotomy and cure of the extrusion, 592

Birmingham General Hospital.—Syphilitic disease of the nervous system, 129

Bristol Royal Infirmary.—Nearly fatal case of poisoning by a known dose of carbolic acid; venous injection of ammonia; recovery, 451—Acute rheumatism, with hyperpyrexia, treated with cold-water coil, 528

Christchurch (Canterbury, New Zealand) Hospital.—Stricture of urethra; dilatation; cure, 734

Cashel Union Hospital.—Empyema; thoracentesis, 492—Surgical cases, 768

Devizes Cottage Hospital.—Ligature of the external iliac, 420

Devon and Exeter Hospital.—Three cases of aneurism successfully treated by digital compression, 311

Dorset County Hospital.—An extensive incised wound through the calf of the leg; important and satisfactory use of the carbolised catgut sutures, 801

Dunedin Hospital.—Fracture of tibia and partial dislocation of astragalus; operation; recovery, 9—Traumatic aneurism; operation; recovery, ib.

Edinburgh Royal Infirmary.—Surgical cases, 169—Extensive burns of lower extremities; recovery, 245—Loose cartilage removed from the knee-joint antiseptically; cure, 311—Anæsthetic leprosy of the left arm; amputation at shoulder-joint; recovery, 420—Two cases of amputation through the hip-joint; recovery, 591

Great Northern Hospital.—Traumatic emphysema without injury to the chest-walls, 129

Guy's Hospital.—Medullary sarcoma of spermatic cord and pelvis; intestinal obstruction; colotomy; temporary relief; death, 128—Cases illustrative of some of the diseases of the rectum, 344, 418—Cancer of the rectum; colotomy; death nine months subsequently, 450—Chloral as a local application for ulcers, 558—Case of empyema treated by free evacuation of the fluid, 624

Hospital for the Epileptic and Paralysed.—Case illustrating the relation betwixt certain cases of migraine and epilepsy, 244

Huntingdon County Hospital.—Epithelioma of the arm, developed on the cicatrix of a burn; amputation; mishap with Esmarch's bandage, 207

King's College Hospital.—Operative interference in cases of cleft palate, 661

Leicester Infirmary.—Dislocation of the sixth cervical vertebra forwards, with fracture of right transverse process and tip of left transverse process; fracture also of both laminæ; death on the seventh day, 346

London Hospital.—Notes of cases of disease of the nervous system, 51—Cases of fistula in ano, 490—Gastrostomy for cancer of the œsophagus, 527—Severe case of iodism; tracheotomy; recovery, 698

Middlesex Hospital.—Cancer of ovaries and peritoneum and umbilicus; compression of the common bile-duct; jaundice; death, 8—Spontaneous cure of an aneurism of the abdominal aorta; death by uræmia, 206—Cases of fissure of the anus, 311—Melanotic sarcoma of femoral glands, secondary to tumour over the heel; sarcomata in spleen and iliac glands, 449—Chronic ulcers in both legs; dry gangrene of both legs—gradual in right, sudden in left, 875

Millbank Prison Hospital.—Persistent headache; partial aphasia; death by coma, 168

Moorfields Ophthalmic Hospital.—Syphilitic keratitis at an unusually early age, 876—Suppuration of the lachrymal sacs in infants, ib.

Newcastle-on-Tyne Infirmary.—Notes on a case of cancer of the stomach, 52—Left hemiplegia; double optic neuritis and syphilitic choroiditis; motor power regained before sensibility; convulsion; death, 346—Male hysteria, ib.

North Riding Infirmary, Middlesborough.—Strangulated inguinal hernia; aspiration; recovery, 278—Loose cartilage in knee-joint; removal on the antiseptic system; recovery, 312

Royal Hants County Hospital.—Severe neuralgia in the tract of the right dental nerve; operation; recovery, 624

Royal Hants Infirmary.—Strangulated inguinal hernia; operation; rapid recovery, 700

Royal Westminster Ophthalmic Hospital.—Cases of glaucoma, 345, 418

St. Antoine Hôpital, Paris.—Cases of syphilitic headache and neuralgia cured by calomel in small and repeated doses, 662

St. Bartholomew's Hospital.—Intense and chronic neuralgia in the tract of the right dental and auriculo-temporal nerves; operation; recovery, 8—Two cases of rheumatism; recovery, 167—Calculus in a girl three years of age, 244—Vesical calculus in a boy eight years of age, with symptoms all his life; lateral lithotomy, 310—Strangulated umbilical hernia in a woman; grangrenous intestine; fæcal fistula made; death six days after operation, 590—Compound depressed fracture of skull; paralysis of right arm; elevation of depressed portion of bone; recovery with useful arm, 733—Hydatid tumour of liver and right pleura; puncture, followed by collapse, peritonitis, and suppuration within the mother cyst; free opening, permitting discharge of numerous hydatid cysts; pleuro-pneumonia; death; autopsy, 799

St. Bartholomew's Hospital, Chatham.—Five cases of ligature of the femoral artery with antiseptic catgut, 835

St. Thomas's Hospital.—Hæmorrhage following tooth extraction, 527—Case of hydrophobia, 589—Aneurismal varix of left common iliac vein; compression of aorta; grangrene of intestine, 834

South London Ophthalmic Holpital.—Two unusual cases of injuries to the eye, 277—Embolism of branches of the arteria centralis retinæ within the eye; with remarks, 491

Stanley Hospital, Liverpool.—Successful amputation at the hip-joint, 699—Successful case of herniotomy; reduction of large masses of omentum, 876

Temporaire Hôpital, Paris.—Case of diabetes, 836

University College Hospital.—Two cases of sloughing of arteries, 50—Depressed fracture of skull; trephining; fungus cerebri; death, 206—Aneurism of the left femoral artery in Hunter's canal; ligature of femoral artery; cure, 557—Two cases of compound fracture of the lower end of the humerus, 767

Warneford Hospital.—Artificial respiration in paralysis of respiratory centres, 558

Westminster Hospital.—Case of septicæmia; periostitis; pericarditis; death in three days, 276—Surgical cases and notes, 662

West London Hospital.—Two cases of retention of urine from laceration of the urethra; catheterism; good results, 277—Two cases of internal urethrotomy for narrow, non-dilatable strictures; good results, 800

York County Hospital.—Ovarian tumour; ovariotomy; recovery, 699
